published studies, the Global Amphibian Assessment, and their own fieldwork.

2. The distance of *Bd* spread was plotted against the years since *Bd* first caused a decline in *Atelopus* populations.
3. Sixty-four frogs, collected before 1987 in Monteverde, Costa Rica, were examined for *Bd* to determine if the pathogen was present prior to the decline.

RESULTS

1. The *Bd* pathogen was not found in frogs collected prior to 1987.
2. The map of *Atelopus* decline from *Bd*'s first appearance in 1987 to nearly 20 years later in 2006 shows that *Bd* spread from Costa Rica to Panama in a wavelike pattern from northwest to southeast.
3. There is a positive linear relationship between *Bd* travel distance and the years since *Bd* infection was detected (see inset on map).

CONCLUSION The analyses of the prevalence of *Bd* in lower Central America over nearly 20 years support a classic pattern of a novel invasive disease spread across naïve populations rather than the environmentally induced emergence of an already existing disease.

work with the data

The researchers were able to combine the distributional data of *Bd* infection from lower Central America with a much larger data set from South America to determine the percentage of *Atelopus* species that became extinct as a function of elevation. They found the following frog species extinctions with elevation:

Elevation (m)	Species extinctions (%)
0-199	30
200-1,000	85
1,001-4,000	100

QUESTIONS

1. The data from the results portion of the experiment can be used to calculate the rate of spread (km/year) of *Bd* by dividing the distance

between pairs of locations (distance interval) by the number of years between the dates of decline. Calculate the rate of spread of the *Bd* pathogen between pairs of locations of frog declines (time interval). Is the rate of *Bd* spread similar among locations, or does it differ?

2. Calculate the average rate of spread for the *Bd* pathogen in lower Central America. Predict how far and in what direction *Bd* could travel by 2016 (10 years).
3. Using the map elevations in the results section of the experiment, and the species extinction data above, is it likely that the *Bd* pathogen will spread, and cause species extinctions, in the direction and distance estimated in your answer to Question 2? If so, what is your best estimate of the percentage of species that would become extinct? Explain.

A similar **work with the data** exercise may be assigned in **LaunchPad**.

Species and ecosystems are already being affected by climate change

As you saw in [Key Concept 57.4](#), human-generated emissions of greenhouse gases are contributing to global climate warming, sea level rise, increased storminess, and ocean acidification, all of which are likely to become increasingly important causes of habitat loss and degradation, and ultimately species extinctions. Across North America, for example, average annual temperatures are predicted to increase by 2°C to 5°C by the end of the twenty-first century. If the climate warms to that extent, model projections show that the average temperature found at any given location in North America today could shift 500-800 kilometers to the north. Those species that cannot adapt to the warmer climate will have to shift their geographic ranges to stay within their physiological and ecological ranges. The shift in distributional range that organisms experience could result in habitat loss and fragmentation, especially if appropriate habitat does not shift as well or is lost altogether.

For example, as the globe warms, sea level is rising as a result of melting polar glaciers and warming seas. The Intergovernmental Panel on Climate Change (IPCC) estimates that the current rate of global sea level rise is 3 millimeters per year, resulting in a projected rise of 0.2-0.5 meters by 2100. As the seas slowly inundate the coast, coastal ecosystems will become increasingly flooded, putting them at great risk for habitat loss. Likewise, as polar regions warm, sea ice ecosystems are disappearing at an alarming rate, affecting species such as polar bears and seals dependent on that habitat (see the Future directions discussion in [Chapter 57](#)). Global

warming has also been implicated in causing more frequent and extreme storm events, as seas warm and winds increase in intensity. Extreme storms such as Hurricane Sandy in 2012 are causing flooding and erosion hazards for both human and natural coastal communities. Finally, as discussed in Investigating Life: Food Webs in an Acidic and Warming Ocean in [Chapter 57](#), as the ocean absorbs more atmospheric CO₂, seas become more acidic, leading to a host of individual species and ecosystem changes.

Scientists are beginning to explore how species and ecosystems will respond to climate change by predicting how it may affect organisms and looking for ways to mitigate those effects. Their research activities include analyses of past climate changes and studies of sites currently undergoing rapid climate change. It would be helpful to know, for example, how rapidly species responded to the end of the most recent ice age. Which species did and did not keep pace with the warming climate and rising seas? How much, and in what ways, do past ecological communities differ from those of today as a result of changes in climate?

Species that can disperse easily, such as birds, insects, and fish that can move considerable distances, may be able to shift their ranges as rapidly as the climate changes, provided they can find appropriate habitats. However, the ranges of other species, particularly plants, are likely to shift more slowly. For example, after the glaciers started to retreat in North America about 18,000 years ago, the ranges of plant communities slowly shifted northward ([Figure 58.11](#)). In addition, roughly 12,000 years ago, some novel, or what are termed "no analog" plant communities, formed under unique climate conditions that do not exist today. Thus it may be that as climate rapidly changes, unique combinations of species will come together to form similar novel communities.

Large areas were once covered by vegetation types that have no modern analog.

Figure 58.11 Past Changes in Plant Communities Due to Climate Vegetation types in eastern North America have changed since the last glacial maximum, 18,000 years ago (ka, thousands of years before present). Vegetation composition was determined from pollen preserved in sediments.

Q: After the glaciers first started to retreat 18,000 years ago, what has been the pattern of plant community change with latitude? What were the "no analog" plant communities, and how did they form?

Modern-day scientific observations have shown that for a wide variety of organisms, latitudinal and elevational distributions are shifting in ways that are consistent with climate change ([Table 58.1](#)). For example, a study that considered the range shifts in alpine plants in the European alps showed that plant species have been moving to higher elevations consistent with increasing temperature. Researchers compared current plant community species richness with historical data from the eighteenth and nineteenth centuries. They found that alpine plant species richness increased over time, suggesting that plants were moving from lower elevations to higher elevations. Likewise, observations of the distribution of nonmigratory butterfly species in Europe and North America showed that of the 39 species examined, 63 percent had moved their ranges northward, while only 3 percent had moved southward.

table 58.1 Recent Latitudinal and Elevational Range Shifts That Likely Result from Climate Change

Community or taxon	Location	Observed changes	Climate link
Tree line	Europe, New Zealand	Elevational shifts from lower to higher mountain zones	Increased air temperature
Alpine plants	European alps	Elevational shifts of 1-4 m per decade	Increased air temperature
Zooplankton, intertidal invertebrate, and fish communities	California coast, North Atlantic Ocean	Increasing abundance of warm-water species	Increased ocean temperature
39 butterfly species	North America, Europe	Northward range shifts up to 200 km over 27 years	Increased air temperature
Lowland birds	Costa Rica	Elevational shifts from lower to higher mountain zones	Decreased dry-season mist frequency
12 bird species	Britain	Northward range shifts up to 19 km over 20 years	Increased winter air temperature
Red fox (<i>Vulpes vulpes</i>), Arctic fox (<i>Alopex lagopus</i>)	Canada	Northward range shift of red fox and simultaneous southward range shift of Arctic fox	Increased air temperature

Along with the shifts in distribution, evidence is mounting that important life history events are also occurring earlier in the spring ([Table 58.2](#)). The observations suggest that increases in temperature are triggering species to breed or migrate earlier than they have in the past few decades. There can also be physiological changes that reduce growth and reproduction. For example, since the mid-1980s the average minimum nightly temperature at La Selva Biological Station in the Caribbean lowlands of Costa Rica has increased from about 20°C to 22°C. On warmer nights, trees use more of their energy reserves to maintain themselves. As a result, even this small rise in temperature has reduced the average growth rate of six different tree species by about 20 percent.

Table 58.2 Recent Advances in the Timing of Life History Events That Likely Result from Climate Change

Taxon	Location	Observed changes	Period
Numerous plant species	Europe	Earlier flowering and leaf unfolding by 1.4-3.1 days per decade	Past 30-48 years
	North America	Earlier flowering and leaf unfolding by 1.2-2.0 days per decade	Past 35-63 years
18 butterfly species	United Kingdom	Earlier appearance by 2.8-3.2 days per decade	Past 23 years
Amphibians	United Kingdom	Earlier breeding	Past 25 years
Numerous bird species	Europe, North America	Earlier spring migration by 1.3-4.4 days per decade and earlier breeding by 1.9-4.8 days per decade	Past 30-60 years

Finally, climate change has the potential to cause species extinctions, although to date, none have been directly and definitively linked to this cause. However, as you saw in [Figure 58.2](#), effects of climate change such as habitat loss or changes in life history or physiology could lead to lower effective population sizes, increased population extinctions, and eventually species extinctions.

58.2 recap

Biodiversity loss is the result of four major, and potentially interacting, factors. First, habitat loss and degradation (including pollution) have been primary culprits contributing to the extinction of tens of thousands of species. Second, overharvesting for food, clothing, ornamentation, pets, and medicines has eased for some species, but others are still under threat. Third, deliberate or inadvertent introduction of non-native species has increased exponentially, with some becoming invasive—meaning they reproduce rapidly, spread widely, and have mostly negative effects on native species. Finally, some species are already affected by climate change through distributional changes, timing of life history events, and decreased growth and reproduction and will continue to be impacted as climate change progresses.

learning outcomes

You should be able to:

- Describe, with examples, how human activities have resulted in habitat loss, fragmentation, and degradation.
- Give examples of situations where birds, mammals, and exotic animals have been overharvested, and describe and analyze the ecological implications of these examples.
- Describe and analyze methods by which species can invade or be introduced into new regions, and infer some possible results of these introductions.
- Correlate changes in climate with changes in species or ecosystems, giving evidence for the correlation.

1. How does habitat fragmentation contribute to the extinction of species?
2. Refer to [Figure 56.9](#). Describe how the loss of wolves has likely resulted in a decrease in hardwood trees in Yellowstone National Park (see [Figure 58.9](#)).
3. Give three reasons why invasive species can have negative effects on biodiversity and ecosystems.
4. Suppose you have ecological data for a species of butterfly over the last 50 years. The data show that this species' range has moved north by 100 km and that its emergence occurs 4 days earlier than 50 years ago. Do these data suggest the butterfly species is responding to climate warming? Explain.

A major objective of understanding how and why biodiversity loss is occurring is to determine how conservation and management strategies might help preserve species. In the next section we will consider some positive steps that are being taken to recover and protect biodiversity.

58.3 Protecting Biodiversity Requires Conservation and Management Strategies

As you have seen multiple times in this chapter, human activities play an integral role in biodiversity loss. Consequently, it falls to humans to develop, strengthen, and defend policies that conserve biodiversity.

focus your learning

Humans are establishing protected areas to preserve biodiversity by restricting habitat loss and degradation.

Coupled human-natural systems are a necessary part of protecting biodiversity.

Captive breeding programs are temporary measures to maintain endangered species while threats in their natural environment are removed.

Biodiversity conservation integrates interests from ecological, institutional, and socioeconomic contexts into the decision-making process ([Figure 58.12](#)). Ecologists use scientific theory, empirical data, and tools from a variety of disciplines to help inform the protection and management of endangered and threatened species and eco-systems. They identify the factors that present risks to species and ecosystems and provide that information to managers, landowners, politicians, lawyers, nonprofit agencies, and the general public so that appropriate decisions can be made and action plans can be devised. Partnerships that incorporate these multiple contexts and stakeholders often result in conservation plans with the most support. Here we consider some conservation actions designed to protect and manage biodiversity in more detail.

Figure 58.12 Humans Are an Integral Part of Protecting and Managing Biodiversity Protecting and managing biodiversity involves integrating interests from ecological, institutional, and socioeconomic contexts. Partnerships that incorporate these multiple contexts (*) often result in conservation plans with the most support.

Protected areas preserve habitat and curtail biodiversity loss

The establishment of [protected areas](#), in which habitat loss or degradation is restricted or prohibited, is probably the most important component of efforts to conserve and manage biodiversity. Protected areas allow populations of multiple species to maintain themselves in the preserved habitat and may also serve as nurseries from which individuals can disperse into unprotected areas, replenishing populations that might otherwise become extinct. Without proper habitat, the long-term preservation of biodiversity will be nearly impossible.

protected areas An area in which habitat loss or degradation by human activity is restricted or prohibited.

Deciding which areas to protect usually involves a complex array of decisions by stakeholders. From an ecological perspective, two criteria need to be met: (1) the candidate habitat must support viable populations of the species it is meant to protect, and (2) the original ecosystem functions and services of the candidate habitat must be mostly intact.

DESIGNING PROTECTED AREAS

The first element in nature-preserve design involves identifying a large area that is relatively undisturbed and can serve as the core of the protected area ([Figure 58.13A](#)). This core natural area should allow populations of endangered species to maintain themselves and potentially serve as source individuals for populations outside the core area. This typically means that the core area should be large and compact with as little edge habitat as possible, to reduce edge effects.

Figure 58.13 Nature Reserve Designs Based on Ecological Principles Some spatial configurations are better than others when designing reserves for fostering biodiversity.

The second element in designing a protected area involves buffer zones around the core area ([Figure 58.13B](#)). Buffer zones have some features required by the species of concern but involve less stringent controls on land use. For example, buffer zones allow some resource extraction (e.g., timber, food, or medicines) or recreation while maintaining some of the original

habitat.

The third element in nature-preserve design involves habitat connectivity ([Figure 58.13C](#)), which keeps populations from becoming isolated from the greater metapopulation and thus subject to extinction (see [Key Concept 54.4](#)). Traveling from one protected habitat to another requires habitat corridors, or patches that connect blocks of suitable habitat. Insight into the importance of corridors has led to new regional conservation initiatives, among the most notable of which is the Yellowstone to Yukon Conservation Initiative. This joint Canada—United States nonprofit organization has as its goal the sustainable preservation of the mountain ecosystem extending from Yellowstone National Park in the United States to Yukon, Canada. This stretch of land, the largest intact ecosystem of its kind on the planet, contains high-quality habitat for many of North America's most imperiled animals, including grizzly bears, gray wolves, lynx, and native fish. The initiative works with landowners to find sustainable ways of preserving high-quality, well-connected wildlife habitat in the region. For example, Banff National Park has 40 human-made corridors for wildlife that cross an 83-kilometer stretch of the Trans-Canada Highway ([Figure 58.14](#)). Managing the entire region in this way will not only provide passageways to habitat for these species, but will also provide room for their populations to shift in response to global climate change.

Figure 58.14 Habitat Corridors: Passageways to Recovery Grizzly bears and other wildlife can use this overpass to travel safely over the Trans-Canada Highway and gain access to more protected area in Banff National Park, Canada.

COUPLED HUMAN—NATURAL SYSTEMS

Establishing protected areas is an essential component of efforts to maintain biodiversity, but this action alone is insufficient to stem global biodiversity loss. The extensive landscapes in which people live and extract resources should be integrated into biodiversity conservation efforts. Even urban and suburban areas can contribute to the conservation of species and habitats. The practice of encouraging biodiversity and sustainability in systems where humans and nature are intricately linked is known as [coupled human—natural system ecology](#).

coupled human–natural system ecology The practice of encouraging biodiversity and sustainability in systems where humans and nature are intricately linked.

Research into coupled human—natural systems builds on the disciplines of ecology, physical sciences, social sciences, and economics. It is based on the principle that most ecosystem services are provided locally, and that people are motivated to work to protect their local interests. In practice, encouraging linkages between humans and nature comes in many forms. For example, the National Wildlife Federation has established a successful program in which people petition to have their backyards certified as wildlife-friendly. Criteria for certification include planting shrubs that provide food for birds and refraining from applying pesticides. In the case of coastal developments exposed to flooding hazards during extreme storms or sea level rise, humans are encouraging the protection and restoration of coastal wetlands and dunes, so-called green infrastructure, which provide important ecosystem services such as coastal protection, biodiversity, and recreation. Peregrine falcons (*Falco peregrinus*), once endangered by pesticide use, are thriving in urban settings where tall buildings mimic the cliffs that peregrines naturally nest on, and non-native pigeons are a main prey item. Green roofs, which are roofs covered with soil and native vegetation, are a way of creating parks and habitat, cooling buildings, and dealing with storm-water runoff, all important ecosystem services to humans. France passed a law in 2015 that requires all new buildings constructed in commercial areas to be partially covered by green roofs or solar panels.

Even some industrial sites can support biodiversity. The Turkey Point power plant in southern Florida uses large amounts of water to cool its generating units. To cool the heated water before discharging it, the Florida Power & Light Company dug a system of 38 canals that covers 2,428 hectares. These cooling canals are separated by low-lying berms that support a variety of native and non-native plants. Red mangroves grow along the edges of the canals. Today they support a thriving population of American crocodiles, a highly endangered species. Crocodiles living in the canals yield about 10 percent of all young crocodiles born in the United States.

Degraded ecosystems can be restored

When a species is endangered as a consequence of habitat degradation rather than outright habitat loss, protecting the species may require restoring the habitat to a more natural state. Without human assistance, many degraded ecosystems recover very slowly, if at all.

Restoration ecology involves renewing degraded ecosystems by active human intervention. Ideally, restoration involves reestablishing the original structure and function of native ecosystems through such techniques as active removal of pollutants or non-native species, revegetation to reestablish habitat and food resources, reintroduction of native species, and reestablishment of hydrological processes or disturbance regimes. For example, many species depend on particular patterns of disturbance, such as fire or windstorms, to maintain their populations (see [Key Concept 56.4](#)).

restoration ecology The science and practice of restoring damaged or degraded ecosystems by active human intervention.

Recognition of the need for periodic disturbance to maintain healthy ecosystems is a relatively new dimension of conservation biology. We know, for example, that many plant species require periodic fires for successful establishment and survival, but for many years the official policy of the U.S. Forest Service, symbolized by the iconic mascot Smokey Bear, was to suppress all forest fires. Today, however, controlled burning is common, particularly in western North America. In order to use fire as an ecosystem management tool, it is important to know the

historical pattern of fires in an area, which can be determined in part by studies of the annual growth rings and fire scars of trees. A schedule of controlled burning that recreates the historical pattern can reduce forest floor litter, avoiding a buildup of fuel that can lead to intense, tree-killing canopy fires.

Sometimes restoration involves using species that act as ecosystem engineers to help restore the original ecosystem. For example, as [Key Concepts 56.3](#) and [Figure 56.12](#) described, the recolonization of beavers, once hunted to near extinction on Minnesota's Kabetogama Peninsula, resulted in more wetlands and higher species diversity as a consequence of the beavers' dam-building activities. You've seen also how vegetation such as grasses can be planted to facilitate sediment capture, accretion, and ultimately the restoration of sea-grass beds, salt marshes, and sand dunes for habitat and coastal protection.

A large-scale terrestrial grassland restoration project—coined the “American Serengeti”—is under way in northeastern Montana. The goal of the project, which is run by the World Wildlife Fund and American Prairie Reserve in cooperation with public land managers and several other private conservation organizations, is to restore and conserve the native prairie and its fauna over a 1.2-million-hectare area near the Missouri River ([Figure 58.15](#)). When Lewis and Clark mapped this region 200 years ago, they saw large herds of bison, elk, deer, and pronghorn as well as abundant populations of their predators. But by the middle of the twentieth century, most North American prairies had been converted to cropland or were heavily grazed by domestic livestock, reducing the herds of large mammals to small remnant populations. Most of these populations are too small to maintain their genetic diversity or to function in their original ecological roles. However, the species have survived, so opportunities exist to reintroduce them if their habitat can be restored.

Figure 58.15 Restoring a North American Prairie (A) A major prairie restoration project (yellow area) is under way north of the Missouri River in Montana. (B) Restoration of prairie ecosystems can be as simple as removing fences that restrict large herds of native grazers such as bison. (C) The first bison were reintroduced to the area in 2005.

This ambitious restoration and protection project is feasible for three reasons. First, the private land in the area is owned by a small number of ranchers, each of whom owns extensive grazing

leases on public lands administered by either U.S. federal agencies or the State of Montana. Second, most of the land has never been plowed, so native vegetation may recover rapidly when grazing pressures are reduced. Third, the area's human population is decreasing. Ranchers are aging, and some of their children are leaving for careers in urban settings. Once free-ranging herds of several thousand bison and large numbers of elk—along with their predators (wolves)—have been established, nature-minded tourists are expected to flock to the area to view the wildlife spectacle. Over the long term, the restored ecosystem should deliver major economic benefits to the region.

Captive breeding programs can maintain a few species

A few of the world's endangered species can be maintained in captivity while the external threats to their persistence are reduced or removed. However, captive propagation is only a temporary measure that buys time to deal with those threats. Zoos, aquariums, and botanical gardens do not have enough space to maintain adequate populations of more than a small fraction of Earth's endangered and threatened species. Nonetheless, captive propagation can play an important role by maintaining species and their genetic diversity during critical periods, providing a source of individuals for reintroduction into the wild, and raising public awareness of threatened and endangered species.

The California condor, North America's largest bird, survives today only because of captive propagation ([Figure 58.16](#)). Two centuries ago, condors ranged from British Columbia to northern Mexico, but by 1978 the wild population was plunging toward extinction. Many of the birds, which are scavengers, had died from ingesting animal carcasses containing lead shot or bullets. To save the condor from certain extinction, the Endangered Species Act was evoked and biologists captured all the remaining condors—only 22 individuals—and initiated a captive breeding program in 1983.

Figure 58.16 California Condors Make a Comeback (A) California condors raised in captivity are fed by humans wearing hand puppets so that the birds will not imprint on their human captors and will be able to survive in the wild. (B) Numbered wing tags allow conservation biologists to identify and track released adult condors. The survival of North America's largest bird species depends on this captive propagation project.

The first captive-bred birds were released in the mountains north of Los Angeles in 1992. Since that time, there have also been releases in northern Arizona and Baja California. Today captive-bred birds use the same roosting sites, bathing pools, and mountain ridges that their wild-born predecessors did. In 2003 a wild-born chick fledged in the wild for the first time in more than two decades. By 2014 the number of condors living in the wild had reached 228, with

another 193 living in captivity. Most of the major threats to condor survival, including power lines, pesticides, and museum collectors, have been mitigated. Lead poisoning is still a problem, but as of July 1, 2008, under the Ridley-Tree Condor Preservation Act, California hunters are required to use non-lead bullets when hunting in the condor's range. Passage of this legislation marks a change in public attitudes from the days when cattle ranchers, in the mistaken belief that the condors killed livestock, opposed their reintroduction into the wild.

Ending trade is crucial to saving some species

Most endangered species cannot survive any further reductions in their breeding populations, so it is important to prevent their exploitation. The legal mechanism for prohibiting trade in these species or their products is an international agreement called the Convention on International Trade in Endangered Species (CITES). CITES currently prohibits international trade in items such as whale meat, rhinoceros horns, and many species of parrots, orchids, and others.

The recent history of elephant poaching for ivory illustrates how complex it can be to prevent hunting of endangered species. CITES instituted a ban on international trade in African elephant ivory in 1989, but demand for ivory remains strong, especially in Asia. As a result, as we described above, poaching of elephants continues in the forests of central and east Africa, where the animals are threatened. However, some countries, including Malawi and Zambia, have so many elephants that government officials kill them to control populations and prevent the animals from damaging crops. This excess of elephants led to the controversial decision to sanction sales of ivory from Namibia, Botswana, Zimbabwe, and South Africa in 2008, the first such sales in close to a decade. More than 100 tons of elephant tusks—the equivalent of 20,000 dead elephants—were auctioned off to authorized buyers from China and Japan and generated \$15 million for elephant conservation efforts. Although the 2008 sales were monitored by CITES, concerns remain that the flood of legal ivory will be intermingled with poached ivory.

Species invasions must be controlled or prevented

The best way to reduce the damage caused by invasive species is to prevent their introduction or eradicate them earlier in their establishment phase. Given the tremendous volume of global trade, curtailing it might seem impossible, but some promising strategies do exist. For example, transoceanic transport of invasive species in ballast water could be largely eliminated by the simple procedure of deoxygenating ballast water before it is pumped out. This practice not only kills most organisms in the water but also extends the life of ballast tanks—an economic benefit to shippers.

In 1996 the U.S. Congress responded to concerns about ballast water with legislative action. After years of wrangling, in 2012 the U.S. Coast Guard amended its regulations on managing ballast water to set standards for “the allowable concentration of living organisms in ballast water discharged from ships in waters of the United States.” Despite the adoption of these strict standards for protecting U.S. waterways, transport of invasive aquatic organisms in ballast water is an international problem whose potential solutions continue to run up against political and economic barriers.

Biodiversity can be conserved as a consequence of its economic value

As we've discussed previously, biodiversity can benefit humans in profound ways, providing important goods and services. You learned in [Key Concept 57.5](#) that ecosystem goods and services can be valued by using a variety of methods to determine what people are willing to pay for them. Some goods such as timber or products from the animal trade are relatively easy to value, but nonmarket services such as the existence of an endangered species or the ability to visit a unique ecosystem are much harder to value. The following examples provide a sense of the nonmarket benefits of conserving rare or endangered species.

WILD DOGS AND ECOTOURISM

Environmentally responsible travel to natural areas, the proceeds of which support conservation efforts and the economic well-being of the local communities, is a major source of income for many developing nations. For example, tourists visiting Africa often express interest in seeing wild dogs (*Lycaon pictus*) ([Figure 58.17](#)). However, diseases such as rabies and canine distemper, along with habitat loss, road kills, deliberate extermination due to a perceived threat to livestock, and many other factors have decimated wild dog populations, making this the second-most endangered carnivore in Africa. (Another canid, the Ethiopian wolf, *Canis simensis*, is first.) South Africa is home to about 400 of Africa's remaining 5,000 wild dogs, most of which live in Kruger National Park. Their endangered status has piqued tourist interest in these charismatic animals; a survey of visitors to South Africa revealed that nearly three-fourths of them would be willing to pay an extra U.S. \$12 for the opportunity to see wild dogs. Conservation biologists are working with lodge owners and ranchers elsewhere in South Africa and in Kenya to encourage them to reestablish wild dogs in areas from which they have disappeared.

Figure 58.17 Tourists Are Willing to Pay to See Wildlife The wild dog (*Lycaon pictus*) is the second-most endangered carnivore in Africa. Tourists come to Kruger National Park in South Africa to catch a glimpse of this rare species.

POLLINATORS AND COFFEE

Taylor Ricketts and colleagues at Stanford University assessed the economic value of the pollination services provided by the bees that live in, and depend on, tropical forest patches adjacent to a coffee plantation in Costa Rica. They found that coffee production was highest at the sites that were closest to forest patches. They also hand-pollinated some coffee plants to show that the difference in production was a result of pollination services rather than other environmental conditions. The investigators calculated that the value of pollination services to the plantation on which the experiments were carried out was about \$60,000 per year, more than the current conservation incentive payments offered to landowners to preserve forest patches.

58.3 recap

Ecologists use scientific theory, empirical data, and tools from a variety of disciplines to help inform socioeconomic and institutional sectors in the protection and management of biodiversity. To achieve these biodiversity conservation goals, various strategies are employed, including creating protected areas, restoring degraded habitat, breeding endangered species in captivity, ending trade of endangered species, controlling species invasions, and making biodiversity a marketable commodity.

learning outcomes

You should be able to:

- List guiding principles behind establishing protected areas and explain the reason for each principle.
- Discuss the benefits and limitations of captive breeding programs as a method for preserving endangered species.

1. Given the principles of reserve design and an understanding of how global warming can affect the distribution of species, design the best possible but realistic protected area for the conservation of terrestrial biodiversity today and in the future.
2. Using the example of the California condor, describe how species recovery is dependent on the integration of ecological information, socioeconomic interests, and institutional authority.

investigatinglife

QA Is the most recent dramatic decline of amphibians the result of a novel fungal pathogen, and if so, what can be done about it?

The research to date suggests that amphibian declines are caused by multiple human-instigated factors, including habitat loss and pollution, overharvesting, and even exposure to UV radiation, but that the final fatal blow may be the unintended introduction of the novel chytrid fungal pathogen *Batrachochytrium dendrobatidis*, or Bd. Population declines and species extinctions of amphibians have occurred at such alarming rates, and in areas that are considered undisturbed, that it can be hard to know how the Bd invasion can be stopped or realistically treated in the wild. Despite these hurdles, scientists are recommending several measures to help control the pathogen's destructive effects. The first and foremost recommendation is to reduce the volume of amphibian trade and ensure that amphibians transported long distances are required by law to undergo disease testing and quarantine procedures. Second, improvements in diagnostics and knowledge of the disease are needed in both wild and captive settings. Recently, a method using PCR has been developed to definitively identify the fungus in the water and on the skin of potentially infected animals. Third, the risk of spread can be minimized by restricting the movement of captive amphibians, especially to the wild, and by disinfecting footwear and collecting equipment when working in aquatic environments. A variety of strategies that integrate ecological research, socioeconomic interests, and institutional authority will likely be required to save the remaining amphibian species that are susceptible to this highly fatal disease.

Future directions

Although it is tragic that the harlequin frog (*Atelopus varius*), once ubiquitous in the mountains of Costa Rica, and the golden frog (*Atelopus zeteki*), the national symbol of Panama, could disappear so fast, hope still remains. An active area of research involves understanding why some amphibian species, such as the American bullfrog and African clawed frog, are more resistant to Bd while other species are highly susceptible. Some mechanisms that could explain species resistance to the disease are (1) the presence of specific types of bacteria or antimicrobial compounds that discourage Bd growth, (2) inherent genetic resistance to Bd, and (3) certain less virulent strains of Bd. More research will be needed to understand the complexities of the disease. In the meantime, captive breeding programs are under way for both the harlequin frog and golden frog so that they might one day be reintroduced into the Costa Rican and Panamanian nature preserves designed to protect them.

► 58.1 Human Activities Are Changing the Biosphere, Resulting in Biodiversity Loss

- Biodiversity has great value to human society in the form of goods and services, but human activities have caused its rapid decline at genetic, population, species, ecosystem, and global scales. **Review Figure 58.1**
- Human-caused events coupled with natural events can reduce a species' **effective population size** (number of individuals that can contribute offspring to the next generation), leading to population and species extinctions. Ever-smaller effective population sizes are affected by inbreeding depression, genetic drift, and **demographic stochasticity**. **Review Focus: Key Figure 58.2**
- Humans are causing biodiversity loss at unprecedented rates, rivaling that of the five previous mass extinction events, which were the result of cataclysmic natural disasters.
- We can estimate the extinction probability of species by taking into account their population sizes, genetic variation, life history traits, and ecology. **Review Figure 58.3**

► 58.2 Most Biodiversity Loss Is Caused by Habitat Loss and Degradation

- **Habitat loss** (reduction in habitat quantity) and **habitat degradation** (reduction in habitat quality) have been the major causes of biodiversity loss. Estimates are that humans have transformed 50%-60% of the land surface, primarily for agriculture, timber, and livestock grazing. **Review Figure 58.4**
- Overharvesting of species for food, clothing, ornamentation, pets, and medicines was once the most important and rapid cause of species extinction and is still a concern for some species if conservation measures are not enacted. **Review Figures 58.7, 58.9**
- Deliberate or inadvertent introductions of non-native species have increased exponentially over the last 200 years, with roughly 10 percent of those species becoming invasive.
- **Invasive** species can endanger native species through predation, competition, and disease. They can cause changes to ecosystem functions or genetic diversity through hybridization with wild populations. **Review Figure 58.10, Investigating Life: Exploring the Decline of Central American Frogs**
- Human-generated emissions of greenhouse gases are contributing to global climate warming, sea level rise, increased storminess, and ocean acidification, all of which are becoming increasingly important causes of biodiversity loss.
- Scientific evidence shows that some species have been, or are currently being, affected by climate change through distributional changes, timing of life history events, and decreased growth and reproduction. **Review Figure 58.11, Tables 58.1, 58.2, Animation 58.1**

► 58.3 Protecting Biodiversity Requires Conservation and Management Strategies

- Ecologists use scientific theory, empirical data, and tools from a variety of disciplines to help inform socioeconomic and institutional sectors in the protection and management of

biodiversity. **Review** [Figure 58.12](#)

- Creating **protected areas** and restoring degraded habitat can curtail biodiversity loss. Creating viable protected areas requires establishing core natural areas, buffer zones surrounding them, and habitat corridors connecting them. **Review** [Figures 58.13](#), [58.14](#)
- **Restoration ecology** involves renewing degraded ecosystems by reestablishing their original structure and function through active removal of pollutants or non-native species, revegetation to reestablish habitat and food resources, reintroduction of native species, or reestablishment of important processes such as disturbance. **Review** [Figure 58.15](#)
- Captive breeding programs and ending trade can help conserve and manage a few highly threatened or charismatic species. **Review** [Figure 58.16](#)
- The best way to reduce the damage caused by invasive species is to either prevent their introduction through trade restrictions or eradicate them in their early establishment phase.
- Biodiversity can be conserved because of the economic value of the goods and services it provides. **Review** [Figure 58.17](#)

Review

- 8.1 Various factors decrease effective population size, eventually leading to extinction.
- 8.1 Biodiversity connects species at all levels; its loss affects population, metapopulation, species, ecosystem, and global levels.
- 8.2 Human-caused habitat loss and degradation are the major causes of biodiversity loss.
- 8.3 Ecologists are establishing protected areas to preserve biodiversity by restricting habitat loss or degradation.
- 8.3 Coupled human-natural systems are a necessary part of protecting biodiversity.

Original Paper: Vickers, T. W. et al. 2015. Survival and mortality of pumas (*Puma concolor*) in a fragmented, urbanizing landscape. *PLoS One* 10(7): e0131490.

Habitat destruction and exploitation as a result of human activities have led to the extinction of many species. One species that is now endangered is the large cat called the puma or cougar (*Puma concolor*). Threats to pumas in southern California include habitat loss, habitat fragmentation, and conflicts with humans, which cause population declines, isolation, and ultimately smaller gene pools for the puma.

Two small puma populations occur in southern California between Los Angeles and San Diego. Earlier studies showed that pumas in both populations had very low genetic diversity, and little or no breeding occurred across populations. The populations are separated by urban and suburban areas, including highways, forming a barrier between the Santa Ana Mountains in the west (the more developed area) and the Peninsular Range to the east. Occasionally, however, pumas have been found to travel through agricultural areas, especially in the Peninsular Range.

Scientists fitted pumas in these populations with radio collars to track them and generate data on survivorship and causes of mortality, with the hope of conserving the populations (see figure). Between 2001 and 2013 they captured, marked, and monitored 74 animals in the two populations. Thirty-one marked animals came from the Santa Ana Mountains and 43 from the Peninsular Range. During the course of the study, 36 of the marked animals died. The table shows the causes of mortality in this sample.

	Number of individuals that died (% of populations)]		
Cause of mortality	Both populations combined	Santa Ana Mountains	Peninsular range

Vehicle collision	10 (28)	6 (46)	4(19)
Legal hunting	6 (17)	0 (0)	6 (26)
Illegal hunting	4 (11)	3 (23)	1 (4)
Suspected disease	4 (11)	1 (8)	3 (13)
Confirmed disease	2 (5)	0 (0)	2 (9)
Fire	2 (5)	1 (8)	1 (4)
Killed for public safety	1 (3)	0 (0)	1 (4)
Killed by other pumas	1 (3)	0 (0)	1 (4)
Capture-related	1 (3)	0 (0)	1 (4)
Unknown	5 (14)	2 (15)	3 (13)
TOTAL	36	13	23

Questions

1. Among the known mortality causes (some are unknown), what are the major causes of death of pumas in these two populations?
2. Using the concept of effective population size, what would the likely effect of reducing puma population sizes be in this region of California?
3. Discuss how maintaining the puma populations in this region contributes to the overall biodiversity of California.
4. Based on the information provided in the text and table, should conservation methods for maintaining and protecting puma populations concentrate on the Santa Ana population, the Peninsular Range population, or both? Explain your answer.
5. How could the concept of coupled human-natural systems be employed to help maintain the puma populations?

APPENDIX A The Tree of Life

Phylogeny is the organizing principle of modern biological taxonomy. A guiding principle of modern phylogeny is monophyly. A monophyletic group is considered to be one that contains an ancestral lineage and all of its descendants. Any such group can be extracted from a phylogenetic tree with a single cut.

The trees shown here provide a guide to the relationships among the major groups of extant (living) organisms in the tree of life as we have presented them throughout this book. The position of the branching “splits” indicates the relative branching order of the lineages of life, but the time scale is not meant to be uniform. In addition, the groups appearing at the branch tips do not necessarily carry equal phylogenetic “weight.” For example, the ginkgo [78] is indeed at the apex of its lineage; this gymnosperm group consists of a single living species. In contrast, a phylogeny of the eudicots [86] could continue on from this point to fill many more trees the size of this one.

The glossary entries that follow are informal descriptions of some major features of the organisms described in [Part Seven](#) of this book. Each entry gives the group’s common name, followed by the formal scientific name of the group (in parentheses). Numbers in square brackets reference the location of the respective groups on the tree.

It is sometimes convenient to use an informal name to refer to a collection of organisms that are not monophyletic but nonetheless all share (or all lack) some common attribute. We call these “convenience terms”; such groups are indicated in these entries by quotation marks, and we do not give them formal scientific names. Examples include “prokaryotes,” “protists,” and “algae.” Note that these groups cannot be removed with a single cut; they represent a collection of distantly related groups that appear in different parts of the tree. We also use quotation marks here to designate two groups of fungi that are not believed to be monophyletic.

Go to **LaunchPad** for interactive versions of these trees, with links to photos, distribution maps, species lists, and identification keys.

Figure A1

Figure A2

Figures A1 and A2 The Tree of Life In this rendition, the prokaryotic lineages are shown in Figure A1 and the eukaryotic lineages are in Figure A2. Among the eukaryotes, the microbial lineages are shown in teal. The eukaryote groups that contain major radiations of large multicellular organisms are shown in brown (brown algae), green (Plantae), orange (fungi), and red (animals).

See the **Interactive Tree of Life** www.Life11e.com/tree

acorn worms (*Enteropneusta*) Benthic marine hemichordates [124] with an acorn-shaped proboscis, a short collar (neck), and a long trunk.

actinobacteria (*Actinobacteria*) [7] Gram-positive bacteria [2] with genomes that have a high ratio of G-C to A-T nucleotide base pairs.

“algae” Convenience term encompassing various distantly related groups of aquatic, photosynthetic eukaryotes [17].

alveolates (*Alveolata*) [18] Unicellular eukaryotes with a layer of flattened vesicles (alveoli) supporting the plasma membrane. Major groups include the dinoflagellates [54], apicomplexans [53], and ciliates [52].

amborella (*Amborella*) [81] An understory shrub or small tree found only on the South Pacific island of New Caledonia. Thought to be the sister group of the remaining living angiosperms [28].

ambulacrarians (*Ambulacraria*) [41] The echinoderms [123] and hemichordates [124].

amniotes (*Amniota*) [49] Mammals, reptiles, and their extinct close relatives. Characterized by many adaptations to terrestrial life, including an amniotic egg (with a unique set of membranes—the amnion, chorion, and allantois), a water-repellant epidermis (with epidermal scales, hair, or feathers), and, in males, a penis that allows internal fertilization.

amoebozoans (*Amoebozoa*) [87] A group of eukaryotes [17] that use lobe-shaped pseudopods for locomotion and to engulf food. Major amoebozoan groups include the loboseans, plasmodial slime molds, and cellular slime molds.

amphibians (*Amphibia*) [133] Tetrapods [48] with glandular skin that lacks epidermal scales, feathers, or hair. Many amphibian species undergo a complete metamorphosis from an aquatic larval form to a terrestrial adult form, although direct development is also common. Major amphibian groups include frogs and toads (anurans), salamanders, and caecilians.

amphipods (*Amphipoda*) Small crustaceans [121] that are abundant in many marine and freshwater habitats. They are important herbi-vores, scavengers, and micropredators, and are an important food source for many aquatic organisms.

angiosperms (*Anthophyta* or *Magnoliophyta*) [28] The flowering plants. Major angiosperm groups include the monocots [85], eudicots [86], and magnoliids [84].

animals (*Animalia* or *Metazoa*) [32] Multicellular heterotrophic eukaryotes. The majority of animals are bilaterians [35]. Other groups of animals include the sponges [33], ctenophores [95], placozoans [99], and cnidarians [100]. The closest living relatives of the animals are the choanoflagellates [94].

annelids (*Annelida*) [110] Segmented worms, including earthworms, leeches, and polychaetes. One of the major groups of lophotrochozoans [37].

anthozoans (*Anthozoa*) One of the major groups of cnidarians [100]. Includes the sea anemones, sea pens, and corals.

anurans (*Anura*) Comprising the frogs and toads, this is the largest group of living amphibians [133]. They are tail-less, with a shortened vertebral column and elongate hind legs modified for jumping. Many species have an aquatic larval form known as a tadpole.

apicomplexans (*Apicomplexa*) [53] Parasitic alveolates [18] characterized by the possession of an apical complex at some stage in the life cycle.

arachnids (*Arachnida*) Chelicerates [119] with a body divided into two parts: a cephalothorax that bears six pairs of appendages (four pairs of which are usually used as legs) and an abdomen that bears the genital opening. Familiar arachnids include spiders, scorpions, mites and ticks, and harvestmen.

arbuscular mycorrhizal fungi (*Glomeromycota*) [91] A group of fungi [30] that associate with plant roots in a close symbiotic relationship.

archaeans (*Archaea*) [3] One of the two primary divisions of life [1]. The term is often used only for the prokaryotic archaeans, which are unicellular organisms that lack a nucleus and lack peptidoglycan in the cell wall. Recent studies indicate that eukaryotes [17] are most closely related to the lokiarchaeotes [12] among the prokaryotic archaeans.

archosaurs (*Archosauria*) [51] A group of reptiles [50] that includes dinosaurs and crocodilians [138]. Most dinosaur groups became extinct at the end of the Cretaceous; birds [137] are the only surviving dinosaurs.

arrow worms (*Chaetognatha*) [101] Small planktonic or benthic predatory marine worms with fins and a pair of hooked, prey-grasping spines on each side of the head.

arthropods (*Arthropoda*) The largest group of ecdysozoans [38]. Arthropods are characterized by a stiff exoskeleton, segmented bodies, and jointed appendages. Includes the chelicerates [119], myriapods [120], crustaceans [121], and hexapods (insects and their relatives) [122].

ascidians (*Ascidacea*) “Sea squirts”; the largest group of tunicates [126]. They are sessile (as adults), marine, saclike filter feeders.

B

bacteria (*Bacteria* or *Eubacteria*) [2] Unicellular organisms lacking a nucleus, possessing distinctive ribosomes and initiator tRNA, and generally containing peptidoglycan in the cell wall. Different bacterial groups are distinguished primarily on nucleotide sequence data. One of the two primary divisions of life [1].

barnacles (*Cirripedia*) Crustaceans [121] that undergo two metamorphoses—first from a feeding planktonic larva to a nonfeeding swimming larva, and then to a sessile adult that forms a “shell” composed of four to eight plates cemented to a hard substrate.

bilaterians (*Bilateria*) [35] Those animal groups characterized by bilateral symmetry and three distinct tissue types (endoderm, ectoderm, and mesoderm). Includes the protostomes [36] and deuterostomes [41].

birds (*Aves*) [137] Feathered, flying (or secondarily flightless) tetrapods [48].

bivalves (*Bivalvia*) Major mollusk [111] group; clams and mussels. Bivalves typically have two similar hinged shells that are each asymmetrical across the midline.

bony vertebrates (*Osteichthyes*) [46] Vertebrates [44] in which the skeleton is usually ossified to form bone. Includes the ray-finned fishes [130], coelacanths [131], lungfishes [132], and tetrapods [48].

brachiopods (*Brachiopoda*) [108] Lophotrochozoans [37] with two similar hinged shells that are each symmetrical across the midline. Superficially resemble bivalve mollusks, except for the shell symmetry.

brittle stars (*Ophiuroidea*) Echinoderms [123] with five long, whip-like arms radiating from a distinct central disk that contains the reproductive and digestive organs.

brown algae (*Phaeophyta*) [57] Multicellular, almost exclusively marine stramenopiles [19] generally containing the pigment fucoxanthin as well as chlorophylls a and c in their chloroplasts.

bryozoans (*Ectoprocta* or *Bryozoa*) [102] A group of marine and freshwater lophotrochozoans [37] that live in colonies attached to substrates; also known as ectoprocts or moss animals. They are the sister group of entoprocts.

C

caecilians (*Gymnophiona*) A group of burrowing or aquatic amphibians [133]. They are elongate, legless, with a short tail (or none at all), reduced eyes covered with skin or bone, and a pair of sensory tentacles on the head.

calcareous sponges (*Calcarea*) [98] Filter-feeding marine sponges with spicules composed of calcium carbonate.

cellular slime molds (*Dictyostelida*) Amoebozoans [87] in which individual amoebas aggregate under stress to form a multicellular pseudoplasmodium.

cephalochordates (*Cephalochordata*) [125] See lancelets.

cephalopods (*Cephalopoda*) Active, predatory mollusks [111] in which the molluscan foot has been modified into muscular hydrostatic arms or tentacles. Includes octopuses, squids, and nautiluses.

cercozoans (*Cercozoa*) [59] Unicellular eukaryotes [17] that feed by means of threadlike pseudopods. Group together with foraminiferans [60] and radiolarians [58] to comprise the rhizarians [20].

charophytes (*Charales*) [70] See stoneworts.

chelicerates (*Chelicerata*) [119] A major group of arthropods [39] with pointed appendages (cheliceræ) used to grasp food (as opposed to the chewing mandibles of most other arthropods). Includes the arachnids, horseshoe crabs, pycnogonids, and extinct sea scorpions.

chimaeras (*Holocephali*) A group of bottom-dwelling, marine, scaleless chondrichthyan fishes [129] with large, permanent, grinding tooth plates (rather than the replaceable teeth found in other chondrichthyans).

chitons (*Polyplacophora*) Flattened, slow-moving mollusks [111] with a dorsal protective calcareous covering made up of eight articulating plates.

chlamydias (*Chlamydiae*) [10] A group of very small Gram-negative bacteria; they live as intracellular parasites of other organisms.

chlorophytes (*Chlorophyta*) [68] The most abundant and diverse group of green algae, including freshwater, marine, and terrestrial forms; some are unicellular, others colonial, and still others multicellular. Chlorophytes use chlorophylls *a* and *c* in their photosynthesis.

choanoflagellates (*Choanozoa*) [94] Unicellular eukaryotes [17] with a single flagellum surrounded by a collar. Most are sessile, some are colonial. The closest living relatives of the animals [32].

chondrichthyans (*Chondrichthyes*) [129] One of the two main groups of jawed vertebrates [45]; includes sharks, rays, and chimaeras. They have cartilaginous skeletons and paired fins.

chordates (*Chordata*) [43] One of the two major groups of deuterostomes [41], characterized by the presence (at some point in development) of a notochord, a hollow dorsal nerve cord, and a post-anal tail. Includes the lancelets [125], tunicates [126], and vertebrates [44].

“chytrids” [89] Convenience term used for a paraphyletic group of mostly aquatic, microscopic fungi [30] with flagellated gametes. Some exhibit alternation of generations.

ciliates (*Ciliophora*) [52] Alveolates [18] with numerous cilia and two types of nuclei (micronuclei and macronuclei).

clitellates (*Clitellata*) Annelids [110] with gonads contained in a swelling (called a clitellum) toward the head of the animal. Includes earthworms (oligochaetes) and leeches.

club fungi (*Basidiomycota*) [93] Fungi [30] that, if multicellular, bear the products of meiosis on

club-shaped basidia and possess a long-lasting dikaryotic stage. Some are unicellular.

club mosses (*Lycopodiophyta*) [74] Vascular plants [25] characterized by microphylls. See lycophytes.

cnidarians (*Cnidaria*) [100] Aquatic, mostly marine eumetazoans [34] with specialized stinging organelles (nematocysts) used for prey capture and defense, and a blind gastrovascular cavity. The sister group of the bilaterians [35].

coelacanths (*Actinista*) [131] A group of marine lobe-limbed vertebrates [47] that was diverse from the Middle Devonian to the Cretaceous, but is now known from just two living species. The pectoral and anal fins are on fleshy stalks supported by skeletal elements, so they are also called lobe-finned fishes.

coleochaetophytes (*Coleochaetales*) [69] Multicellular green algae characterized by flattened growth form composed of thin-walled cells. Thought to be the sister-group to the stoneworts [70] plus land plants [24].

conifers (*Pinophyta* or *Coniferophyta*) [80] Cone-bearing, woody seed plants [26].

copepods (*Copepoda*) Small, abundant crustaceans [121] found in marine, freshwater, or wet terrestrial habitats. They have a single eye, long antennae, and a body shaped like a teardrop.

craniates (*Craniata*) Some biologist exclude the hagfishes [127] from the vertebrates [44], and use the term craniates to refer to the two groups combined.

crenarchaeotes (*Crenarchaeota*) [15] A major and diverse group of prokaryotic archaeans [3], defined on the basis of rRNA base sequences. Many are extremophiles (inhabit extreme environments), but the group may also be the most abundant archaeans in the marine environment.

crinoids (*Crinoidea*) Echinoderms [123] with a mouth surrounded by feeding arms, and a U-shaped gut with the mouth next to the anus. They attach to the substratum by a stalk or are free-swimming. Crinoids were abundant in the middle and late Paleozoic, but only a few hundred species have survived to the present. Includes the sea lilies and feather stars.

crocodilians (*Crocodylia*) [138] A group of large, predatory, aquatic archosaurs [51]. The closest living relatives of birds [137]. Includes alligators, caimans, crocodiles, and gharials.

crustaceans (*Crustacea*) [121] Major group of marine, freshwater, and terrestrial arthropods [39] with a head, thorax, and abdomen (although the head and thorax may be fused), covered with a thick exoskeleton, and with two-part appendages. Crustaceans undergo metamorphosis from a nauplius larva. Includes decapods, isopods, krill, barnacles, amphipods, copepods, and ostracods.

ctenophores (*Ctenophora*) [95] Radially symmetrical, gelatinous marine animals [32], with eight rows of fused plates of cilia (called ctenes).

cyanobacteria (*Cyanobacteria*) [8] A group of unicellular, colonial, or filamentous bacteria that conduct photosynthesis using chlorophyll *a*.

cycads (*Cycadophyta*) [77] Palmlike gymnosperms with large, compound leaves.

cyclostomes (*Cyclostomata*) This term refers to the possibly monophyletic group of lampreys [128] and hagfishes [127]. Molecular data support this group, but morphological data suggest that lampreys are more closely related to jawed vertebrates [45] than to hagfishes.

D

decapods (*Decapoda*) A group of marine, freshwater, and semiterrestrial crustaceans [121] in which five of the eight pairs of thoracic appendages function as legs (the other three pairs, called maxillipeds, function as mouthparts). Includes crabs, lobsters, crayfishes, and shrimps.

demosponges (*Demospongiae*) [97] The largest of the three groups of sponges [33], accounting for 90 percent of all sponge species. Demosponges have spicules made of silica, spongin fiber (a protein), or both.

deuterostomes (*Deuterostomia*) [41] One of the two major groups of bilaterians [35], in which the mouth forms at the opposite end of the embryo from the blastopore in early development (contrast with protostomes). Includes the ambulacrarians [42] and chordates [43].

diatoms (*Bacillariophyta*) [56] Unicellular, photosynthetic stramenopiles [19] with glassy cell walls in two parts.

dikaryotic fungi (*Dikarya*) [31] A group of fungi [30] in which two genetically different haploid nuclei coexist and divide within the same hypha; includes club fungi [93] and sac fungi [92].

dinoflagellates (*Dinoflagellata*) [54] A group of alveolates [18] usually possessing two flagella, one in an equatorial groove and the other in a longitudinal groove; many are photosynthetic.

dinosaurs (*Dinosauria*) A group of archosaurs [51] that includes birds [137] as well as many extinct groups from the Mesozoic era. Extinct Mesozoic dinosaurs included some of the largest terrestrial vertebrates that have ever lived. Informally, many people use the term to refer only to the extinct Mesozoic species.

diplomonads (*Diplomonadida*) [61] A group of eukaryotes [17] lacking mitochondria; most have two nuclei, each with four associated flagella.

dry-nosed primates (*Haplorhini*) A group of primate mammals [134] that includes apes, monkeys, and tarsiers.

E

ecdysozoans (*Ecdysozoa*) [38] One of the two major groups of protostomes [36], characterized by periodic molting of their exoskeletons. Nematodes [116] and arthropods [39] are the largest ecdysozoan groups.

echinoderms (*Echinodermata*) [123] A major group of marine deuterostomes [41] with fivefold radial symmetry (at some stage of life) and an endoskeleton made of calcified plates and spines. Includes sea stars, crinoids, sea urchins, sea cucumbers, and brittle stars.

elasmobranchs (*Elasmobranchii*) The largest group of chondrichthyan fishes [129]. Includes sharks, skates, and rays. In contrast to the other group of living chondrichthyans (the chimaeras), they have replaceable teeth.

embryophytes See land plants [24].

entoprocts (*Entoprocta*) [103] A group of marine and freshwater lophotrochozoans [37] that live as single individuals or in colonies attached to substrates. They are the sister group of bryozoans, from which they differ in having both their mouth and anus inside the lophophore (the anus is outside the lophophore in bryozoans).

eudicots (*Eudicotyledones*) [86] A group of angiosperms [28] with pollen grains possessing three openings. Typically with two cotyledons, net-veined leaves, taproots, and floral organs typically in multiples of four or five.

euglenids (*Euglenida*) [64] Flagellate excavates characterized by a pellicle composed of spiraling strips of protein under the plasma membrane; the mitochondria have disk-shaped cristae. Some are photosynthetic.

eukaryotes (*Eukarya*) [17] Organisms made up of one or more complex cells in which the genetic material is contained in nuclei. Contrast with archaeans [3] and bacteria [2].

eumetazoans (*Eumetazoa*) [34] A group of animals [32] characterized by body symmetry, a gut, a nervous system, specialized types of cell junctions, and well-organized tissues in distinct cell

layers.

euphyllophytes (*Euphyllophyta*) The group of vascular plants [25] that is sister to the lycophytes [74] and which includes all plants with megaphylls.

euryarchaeotes (*Euryarchaeota*) [16] A major group of prokaryotic archaeans [3], diagnosed on the basis of rRNA sequences. Includes many methanogens, extreme halophiles, and thermophiles.

eutherians (*Eutheria*) A group of viviparous mammals [134], eutherians are well developed at birth (contrast to prototherians and marsupials, the other two groups of mammals). Most familiar mammals outside the Australian and South American regions are eutherians (see Table 33.1).

excavates (*Excavata*) [21] Diverse group of unicellular, flagellate eukaryotes, many of which possess a feeding groove; some lack mitochondria.

F

ferns (*Pteridopsida* or *Polypodiopsida*) [76] Vascular plants [25] usually possessing large, frondlike leaves and possessing thin-walled sporangia.

firmicutes (*Firmicutes*) [6] Mostly Gram-positive bacteria [2] with genomes that have a low ratio of G-C to A-T nucleotide base pairs.

flatworms (*Platyhelminthes*) [104] A group of dorsoventrally flattened and generally elongate soft-bodied lophotrochozoans [37]. May be free-living or parasitic, found in marine, freshwater, or damp terrestrial environments. Major flatworm groups include the tapeworms, flukes, monogeneans, and turbellarians.

flowering plants See angiosperms [28].

flukes (*Trematoda*) A group of wormlike parasitic flatworms [104] with complex life cycles that involve several different host species. May be paraphyletic with respect to tapeworms.

foraminiferans (*Foraminifera*) [60] Amoeboid organisms with fine, branched pseudopods that form a food-trapping net. Most produce external shells of calcium carbonate.

fungi (*Fungi*) [30] Eukaryotic heterotrophs with absorptive nutrition based on extracellular digestion; cell walls contain chitin. Major fungal groups include the microsporidia [88], “chytrids” [89], “zygospore fungi” [90], arbuscular mycorrhizal fungi [91], sac fungi [92], and club fungi [93].

G

gastropods (*Gastropoda*) The largest group of mollusks [111]. Gastropods possess a well-defined head with two or four sensory tentacles (often terminating in eyes) and a ventral foot. Most species have a single coiled or spiraled shell. Common in marine, freshwater, and terrestrial environments.

gastrotrichs (*Gastrotricha*) [106] Tiny (0.06–3.0 mm), elongate acoelomate lophotrochozoans [37] that are covered in cilia. They live in marine, freshwater, and wet terrestrial habitats. They are simultaneous hermaphrodites.

ginkgo (*Ginkgophyta*) [78] A gymnosperm [27] group with only one living species. The ginkgo seed is surrounded by a fleshy tissue not derived from an ovary wall and hence not a fruit.

glass sponges (*Hexactinellida*) [96] Sponges [33] with a skeleton composed of four- and/or six-pointed spicules made of silica.

glaucophytes (*Glaucophyta*) [66] Unicellular freshwater algae with chloroplasts containing traces of peptidoglycan, the characteristic cell wall material of bacteria.

gnathostomes (*Gnathostomata*) See jawed vertebrates [45].

gnetophytes (*Gnetophyta*) [79] A gymno-sperm [27] group with three very different lineages; all have wood with vessels, unlike other gymnosperms.

green plants (*Viridiplantae*) [23] Organisms with chlorophylls *a* and *b*, cellulose-containing cell walls, starch as a carbohydrate storage product, and chloroplasts surrounded by two membranes.

gymnosperms (*Gymnospermae*) [27] Seed plants [26] with seeds “naked” (i.e., not enclosed in carpels). Probably monophyletic, but status still in doubt. Includes the conifers [80], gnetophytes [79], ginkgo [78], and cycads [77].

H

hadobacteria (*Hadobacteria*) [4] A group of extremophilic bacteria [2] that includes the genera *Deinococcus* and *Thermus*.

hagfishes (*Myxini*) [127] Elongate, slimy-skinned vertebrates [44] with three small accessory hearts, a partial cranium, and no stomach or paired fins. See *also* craniata; cyclostomes.

hemichordates (*Hemichordata*) [124] One of the two primary groups of ambulacrarians [42]; marine wormlike organisms with a three-part body plan.

heteroloboseans (*Heterolobosea*) [63] Colorless excavates [21] that can transform among amoeboid, flagellate, and encysted stages.

hexapods (*Hexapoda*) [122] Major group of arthropods [39] characterized by a reduction (from the ancestral arthropod condition) to six walking appendages, and the consolidation of three body segments to form a thorax. Includes insects and their relatives (see Table 23.2).

hornworts (*Anthocerophyta*) [73] Nonvascular plants with sporophytes that grow from the base. Cells contain a single large, platelike chloroplast.

horsehair worms (*Nematomorpha*) [115] A group of very thin, elongate, wormlike freshwater ecdysozoans [38]. Largely nonfeeding as adults, they are parasites of insects and crayfish as larvae.

horseshoe crabs (*Xiphosura*) Marine chelicerates [119] with a large outer shell in three parts: a carapace, an abdomen, and a tail-like telson. There are only five living species, but many additional species are known from fossils.

horsetails (*Sphenophyta* or *Equisetophyta*) [75] Vascular plants [25] with reduced megaphylls in whorls.

hydrozoans (*Hydrozoa*) A group of cnidarians [100]. Most species go through both polyp and medusa stages, although one stage or the other is eliminated in some species.

hyperthermophilic bacteria [5] A group of thermophilic bacteria [2] that live in volcanic vents, hot springs, and in underground oil reservoirs; includes the genera *Aquifex* and *Thermotoga*.

I

insects (*Insecta*) The largest group within the hexapods [122]. Insects are characterized by exposed mouthparts and one pair of antennae containing a sensory receptor called a Johnston's organ. Most have two pairs of wings as adults. There are more described species of insects than all other groups of life [1] combined, and many species remain to be discovered. The major insect groups are described in Table 23.2.

“invertebrates” Convenience term encompassing any animal [32] that is not a vertebrate [44].

isopods (*Isopoda*) Crustaceans [121] characterized by a compact head, unstalked compound eyes, and mouthparts consisting of four pairs of appendages. Isopods are abundant and widespread in salt, fresh, and brackish water, although some species (the sow bugs) are

terrestrial.

J

jawed vertebrates (*Gnathostomata*) [45] A major group of vertebrates [44] with jawed mouths. Includes chondrichthyans [129], ray-finned fishes [130], and lobe-limbed vertebrates [47].

K

kinetoplastids (*Kinetoplastida*) [65] Unicellular, flagellate organisms characterized by the presence in their single mitochondrion of a kinetoplast (a structure containing multiple, circular DNA molecules).

kinorhynchs (*Kinorhyncha*) [113] Small (1 mm) marine ecdysozoans [38] with bodies in 13 segments and a retractable proboscis.

korarchaeotes (*Korarchaeota*) A group of prokaryotic archaeans [3] known only by evidence from nucleic acids derived from hot springs.

krill (*Euphausiacea*) A group of shrimplike marine crustaceans [121] that are important components of the zooplankton.

L

lampreys (*Petromyzontiformes*) [128] Elongate, eel-like vertebrates [44] that often have rasping and sucking disks for mouths.

lancelets (*Cephalochordata*) [125] A group of weakly swimming, eel-like benthic marine chordates [43].

land plants (*Embryophyta*) [24] Plants with embryos that develop within protective structures; also called embryophytes. Both sporophytes and gametophytes of land plants are multicellular. Land plants possess a cuticle. Major groups are the liverworts [71], mosses [72], hornworts [73], and vascular plants [25].

larvaceans (*Larvacea*) Solitary, planktonic tunicates [126] that retain both notochords and nerve cords throughout their lives.

lepidosaurs (*Lepidosauria*) [135] Reptiles [50] with overlapping scales. Includes tuataras and squamates (lizards, snakes, and amphisbaenians).

life (*Life*) [1] The monophyletic group that includes all known living organisms. Characterized by a nucleic-acid based genetic system (DNA or RNA), metabolism, and cellular structure. Some parasitic forms, such as viruses, have secondarily lost some of these features and rely on the cellular environment of their host.

liverworts (*Hepatophyta*) [71] Nonvascular plants lacking stomata; stalk of sporophyte elongates along its entire length.

lobe-limbed vertebrates (*Sarcopterygii*) [47] One of the two major groups of bony vertebrates [46], characterized by jointed appendages (paired fins or limbs).

loboseans (*Lobosea*) A group of unicellular amoebozoans [87]; includes the most familiar amoebas (e.g., *Amoeba proteus*).

lokiarchaeotes (*Lokiarchaeota*) [12] A group of prokaryotic archaeans [3] known from deep-sea hydrothermal vents. Among the known prokaryotic archaeans, they are the closest relatives of the eukaryotes [17].

“lophophorates” Convenience term used to describe several groups of lophotrochozoans [37] that have a feeding structure called a lophophore (a circular or U-shaped ridge around the mouth that bears one or two rows of ciliated, hollow tentacles). Not a monophyletic group.

lophotrochozoans (*Lophotrochozoa*) [37] One of the two main groups of protostomes [36]. This group is morphologically diverse, and is supported primarily on information from gene sequences. Includes bryozoans and entoprocts [103], flatworms [104], rotifers and gastrotrichs [106], ribbon worms [107], brachiopods [108], phoronids [109], annelids [110], and mollusks [111].

loriciferans (*Loricifera*) [114] Small (1 mm) ecdysozoans [38] with bodies in four parts, covered with six plates.

lungfishes (*Dipnoi*) [132] A group of aquatic lobe-limbed vertebrates [47] that are the closest living relatives of the tetrapods [48]. They have a modified swim bladder used to absorb oxygen from air, so some species can survive the temporary drying of their habitat.

lycophytes (*Lycopodiophyta*) [74] Vascular plants [25] characterized by microphylls; includes club mosses, spike mosses, and quillworts.

M

magnoliids (*Magnoliidae*) [84] A major group of angiosperms [28] possessing two cotyledons and pollen grains with a single opening. The group is defined primarily by nucleotide sequence data; it is more closely related to the eudicots and monocots than to three other small angiosperm groups.

mammals (*Mammalia*) [134] A group of tetrapods [48] with hair covering all or part of their skin; -females produce milk to feed their developing young. Includes the prototherians, marsupials, and eutherians.

mandibulates (*Mandibulata*) [40] Arthropods [39] that include mandibles as mouth parts. Includes myriapods [120], crustaceans [121], and hexapods [122].

marsupials (*Marsupialia*) Mammals [134] in which the female typically has a marsupium (a pouch for rearing young, which are born at an extremely early stage in development). Includes such familiar mammals as opossums, koalas, and kangaroos.

metazoans (*Metazoa*) See animals [32].

microbial eukaryotes See “protists.”

microsporidia (*Microsporidia*) [88] A group of parasitic unicellular fungi [30] that lack mitochondria and have walls that contain chitin.

mollusks (*Mollusca*) [111] One of the major groups of lophotrochozoans [37], mollusks have bodies composed of a foot, a mantle (which often secretes a hard, calcareous shell), and a visceral mass. Includes monoplacophorans, chitons, bivalves, gastropods, and cephalopods.

monilophytes (*Monilophyta*) A group of vascular plants [25], sister to the seed plants [26], characterized by overtopping and possession of megaphylls; includes the horsetails [75] and ferns [76].

monocots (*Monocotyledones*) [85] Angiosperms [28] characterized by possession of a single cotyledon, usually parallel leaf veins, a fibrous root system, pollen grains with a single opening, and floral organs usually in multiples of three.

monogeneans (*Monogenea*) A group of ectoparasitic flatworms [104].

monoplacophorans (*Monoplacophora*) Mollusks [111] with segmented body parts and a single, thin, flat, rounded, bilateral shell.

mosses (*Bryophyta*) [72] Nonvascular plants with true stomata and erect, “leafy” gametophytes; sporophytes elongate by apical cell division.

moss animals See bryozoans [102].

mycoplasmas Firmicutes [6] that lack cell walls and are among the smallest known cellular organisms.

myriapods (*Myriapoda*) [120] Arthropods [39] characterized by an elongate, segmented trunk with many legs. Includes centipedes and millipedes.

N

nanoarchaeotes (*Nanoarchaeota*) A group of extremely small, thermophilic, prokaryotic archaeans [3] with a much-reduced genome. The only described example can survive only when attached to a host organism.

nematodes (*Nematoda*) [116] A very large group of elongate, unsegmented ecdysozoans [38] with thick, multilayer cuticles. They are among the most abundant and diverse animals, although most species have not yet been described. Include free-living predators and scavengers, as well as parasites of most species of land plants [24] and animals [32].

neognaths (*Neognathae*) The main group of birds [137], including all living species except the ostrich, emu, rheas, kiwis, cassowaries, and tinamous. See palaeognaths.

neopterans (*Neoptera*) The largest group of flying (winged) hexapods [122], recognizable by the fact that they can fold their wings out of the way upon landing.

O

oligochaetes (*Oligochaeta*) Annelid [110] group whose members lack parapodia, eyes, and anterior tentacles, and have few setae. Earthworms are the most familiar oligochaetes.

onychophorans (*Onychophora*) [118] Elongate, segmented ecdysozoans [38] with many pairs of soft, unjointed, claw-bearing legs. Also known as velvet worms.

oomycetes (*Oomycota*) [55] Water molds and relatives; absorptive heterotrophs with nutrientabsorbing, filamentous hyphae.

opisthokonts (*Opisthokonta*) [29] A group of eukaryotes [17] in which the flagellum on motile cells, if present, is posterior. The opisthokonts include the fungi [30], animals [32], and choano-flagellates [94].

ostracods (*Ostracoda*) Marine and freshwater crustaceans [121] that are laterally compressed and protected by two clamlike calcareous or chitinous shells.

P

palaeognaths (*Palaeognathae*) A group of secondarily flightless or weakly flying birds [137]. Includes the flightless ostrich, emu, rheas, kiwis, and cassowaries, and the weakly flying tinamous.

parabasalids (*Parabasalia*) [62] A group of unicellular eukaryotes [17] that lack mitochondria; they possess flagella in clusters near the anterior of the cell.

phoronids (*Phoronida*) [109] A small group of sessile, wormlike marine lophotrochozoans [37] that secrete chitinous tubes and feed using a lophophore.

placoderms (*Placodermi*) An extinct group of jawed vertebrates [45] that lacked teeth. Placoderms were the dominant predators in Devonian oceans.

placozoans (*Placozoa*) [99] A poorly known group of structurally simple, asymmetrical, flattened, transparent animals found in coastal marine tropical and subtropical seas. Most evidence suggests that placozoans are secondarily simplified eumetazoans [34].

Plantae (*Plantae*) [22] The most broadly defined plant group, corresponding to the group that descended from the primary endosymbiotic event that gave rise to chloroplasts. Includes green

plants [23] as well as glaucophytes [66] and red algae [67]. In most parts of this book, we use the word **plant** as synonymous with land plant [24], a more restrictive definition.

plasmodial slime molds (*Myxogastriida*) Amoebozoans [87] that in their feeding stage consist of a coenocyte called a plasmodium.

pogonophorans (*Pogonophora*) Deep-sea annelids [110] that lack a mouth or digestive tract; they feed by taking up dissolved organic matter, facilitated by endosymbiotic bacteria in a specialized organ (the trophosome).

polychaetes (*Polychaeta*) A group of mostly marine annelids [110] with one or more pairs of eyes and one or more pairs of feeding tentacles; parapodia and setae extend from most body segments. May be paraphyletic with respect to the clitellates.

priapulids (*Priapulida*) [112] A small group of cylindrical, unsegmented, wormlike marine ecdysozoans [38] that takes its name from its phallic appearance.

primates (*Primates*) A group of mammals [134] that includes apes, monkeys, tarsiers, lemurs, and lorises.

“prokaryotes” Not a monophyletic group; as commonly used, includes the bacteria [2] and prokaryotic archaeans [3]. A term of convenience encompassing all cellular organisms that are not eukaryotes.

progymnosperms (*Progymnospermophyta*) An extinct group of seedless, vascular plants [25] that were among the first large, woody trees; lived in the Middle Devonian and Early Carboniferous periods.

proteobacteria (*Proteobacteria*) [11] A large and extremely diverse group of Gram-negative bacteria that includes many pathogens, nitrogen fixers, and photosynthesizers. Includes the alpha, beta, gamma, delta, and epsilon proteobacteria.

“protists” This term of convenience is used to encompass a large number of distinct and distantly related groups of eukaryotes, many but far from all of which are microbial and unicellular. Essentially a “catch-all” term for any eukaryote group not contained within the land plants [24], fungi [30], or animals [32].

protostomes (*Protostomia*) [36] One of the two major groups of bilaterians [35]. In protostomes, the mouth typically forms from the blastopore (if present) in early development (contrast with deuterostomes). The major protostome groups are the lophotrochozoans [37] and ecdysozoans [38].

prototherians (*Prototheria*) A mostly extinct group of mammals [134], common during the Cretaceous and early Cenozoic. The five living species—four echidnas and the duck-billed platypus—are the only extant egg-laying mammals.

pterobranchs (*Pterobranchia*) A small group of sedentary marine hemichordates [124] that live in tubes secreted by the proboscis. They have one to nine pairs of arms, each bearing long tentacles that capture prey and function in gas exchange.

pterygotes (*Pterygota*) Flying (winged) insects, the largest group of hexapods [122].

pycnogonids (*Pycnogonida*) Treated in this book as a group of chelicerates [119], but sometimes considered an independent group of arthropods [39]. Pycnogonids have reduced bodies and very long, slender legs. Also called sea spiders.

R

radiolarians (*Radiolaria*) [58] Amoeboid organisms with needlelike pseudopods supported by microtubules. Most have glassy internal skeletons.

ray-finned fishes (*Actinopterygii*) [130] A highly diverse group of freshwater and marine bony

vertebrates [46]. They have reduced swim bladders that often function as hydrostatic organs and fins supported by soft rays (lepidotrichia). Includes most familiar fishes.

red algae (*Rhodophyta*) [67] Mostly multicellular, marine and freshwater algae characterized by the presence of phycoerythrin in their chloroplasts.

reptiles (*Reptilia*) [50] One of the two major groups of extant amniotes [49], supported on the basis of similar skull structure and gene sequences. The term “reptiles” traditionally excluded the birds [137], but the resulting group is then clearly paraphyletic. As used in this book, the reptiles include turtles [136], lepidosaurs [135], birds [137], and crocodilians [138].

rhizarians (*Rhizaria*) [20] Mostly amoeboid unicellular eukaryotes with pseudopods, many with external or internal shells. Includes the foraminiferans [60], cercozoans [59], and radiolarians [58].

rhyniophytes (*Rhyniophyta*) A group of early vascular plants [25] that appeared in the Silurian and became extinct in the Devonian. Possessed dichotomously branching stems with terminal sporangia but no true leaves or roots.

ribbon worms (*Nemertea*) [107] A group of unsegmented lophotrochozoans [37] with an eversible proboscis used to capture prey. Mostly marine, but some species live in fresh water or on land.

rotifers (*Rotifera*) [105] Tiny (0.5 mm) lophotrochozoans [37] with a pseudocoelomic body cavity that functions as a hydrostatic organ, and a ciliated feeding organ called the corona that surrounds the head. Rotifers live in freshwater and wet terrestrial habitats.

roundworms (*Nematoda*) [116] See nematodes.

S

sac fungi (*Ascomycota*) [92] Fungi that bear the products of meiosis within sacs (asci) if the organism is multicellular. Some are unicellular.

salamanders (*Caudata*) A group of amphibians [133] with distinct tails in both larvae and adults and limbs set at right angles to the body.

salps See thaliaceans.

sarcopterygians (*Sarcopterygii*) [47] See lobe-limbed vertebrates.

scyphozoans (*Scyphozoa*) Marine cnidarians [100] in which the medusa stage dominates the life cycle. Commonly known as jellyfish.

sea cucumbers (*Holothuroidea*) Echinoderms [123] with an elongate, cucumber-shaped body and leathery skin. They are scavengers on the ocean floor.

sea spiders See pycnogonids.

sea squirts See ascidians.

sea stars (*Asteroidea*) Echinoderms [123] with five (or more) fleshy “arms” radiating from an indistinct central disk. Also called starfishes.

sea urchins (*Echinoidea*) Echinoderms [123] with a test (shell) that is covered in spines. Most are globular in shape, although some groups (such as the sand dollars) are flattened.

“**seed ferns**” A paraphyletic group of loosely related, extinct seed plants that flourished in the Devonian and Carboniferous. Characterized by large, frondlike leaves that bore seeds.

seed plants (*Spermatophyta*) [26] Heterosporous vascular plants [25] that produce seeds; most produce wood; branching is axillary (not dichotomous). The major seed plant groups are gymnosperms [27] and angiosperms [28].

simians (*Simiiformes*) A group of primate mammals [134] that consists of apes and monkeys.

sow bugs See isopods.

spirochetes (*Spirochaetes*) [9] Motile, Gramnegative bacteria with a helically coiled structure and characterized by axial filaments.

sponges (*Porifera*) [33] A group of relatively asymmetric, filter-feeding animals that lack a gut or nervous system and generally lack differentiated tissues. Includes glass sponges [96], demosponges [97], and calcareous sponges [98].

springtails (*Collembola*) Wingless hexapods [122] with springing structures on the third and fourth segments of their bodies. Springtails are extremely abundant in some environments (especially in soil, leaf litter, and vegetation).

squamates (*Squamata*) The major group of lepidosaurs [135], characterized by the possession of movable quadrate bones (which allow the upper jaw to move independently of the rest of the skull) and hemipenes (a paired set of eversible penises, or penes) in males. Includes the lizards (a paraphyletic group), snakes, and amphisbaenians.

staphylococci (*Staphylococcus*) Firmicutes [6] that are abundant on the surface of the human body; can cause skin diseases and respiratory, intestinal, and wound infections.

star anise (*Austrobaileyales*) [83] A group of woody angiosperms [28] thought to be the sister-group of the clade of flowering plants that includes eudicots [86], monocots [85], and magnoliids [84].

starfish (*Asteroidea*) See sea stars.

stoneworts (*Charales*) [70] Multicellular green algae with branching, apical growth and plasmodesmata between adjacent cells. The closest living relatives of the land plants [24], they retain the egg in the parent organism.

stramenopiles (*Heterokonta* or *Stramenopila*) [19] Organisms having, at some stage in their life cycle, two unequal flagella, the longer possessing rows of tubular hairs. Chloroplasts, when present, surrounded by four membranes. Major stramenopile groups include the brown algae [57], diatoms [56], and oomycetes [55].

streptophytes (*Streptophyta*) All green plants [23] other than chlorophytes [68].

T

tapeworms (*Cestoda*) Parasitic flatworms [104] that live in the digestive tracts of vertebrates as adults, and usually in various other species of animals as juveniles.

tardigrades (*Tardigrada*) [117] Small (0.5 mm) ecdysozoans [38] with fleshy, unjointed legs and no circulatory or gas exchange organs. They live in marine sands, in temporary freshwater pools, and on the water films of plants. Also called water bears.

tetrapods (*Tetrapoda*) [48] The major group of lobe-limbed vertebrates [47]; includes the amphibians [133] and the amniotes [49]. Named for the presence of four jointed limbs (although limbs have been secondarily reduced or lost completely in several tetrapod groups).

thaliaceans (*Thaliacea*) A group of solitary or colonial planktonic marine tunicates [126]. Also called salps.

thaumarchaeotes (*Thaumarchaeota*) [14] A group of prokaryotic archaeans [3] known only from hot environments; they oxidize ammonia and are thought to play an important role in the nitrogen cycle.

therians (*Theria*) Mammals [134] characterized by viviparity (live birth). Includes eutherians and marsupials.

theropods (*Theropoda*) Archosaurs [51] with bipedal stance, hollow bones, a furcula (“wishbone”), elongated metatarsals with three-fingered feet, and a pelvis that points backwards. Includes many well-known extinct dinosaurs (such as *Tyrannosaurus rex*), as well as the living birds [137].

tracheophytes See vascular plants [25].

trilobites (*Trilobita*) An extinct group of arthropods [39] related to the chelicerates [119]. Trilobites flourished from the Cambrian through the Permian.

tuataras (*Rhynchocephalia*) A group of lepidosaurs [135] known mostly from fossils; there is only one living tuatara species. The quadrate bone of the upper jaw is fixed firmly to the skull. Sister group of the squamates.

tunicates (*Tunicata*) [126] A group of chordates [43] that are mostly saclike filter feeders as adults, with motile larval stages that resemble tadpoles.

turbellarians (*Turbellaria*) A group of free-living, generally carnivorous flatworms [104]. Their monophyly is questionable.

turtles (*Testudines*) [136] A group of reptiles [50] with a bony carapace (upper shell) and plastron (lower shell) that encase the body in a fashion unique among the vertebrates.

U

urochordates (*Tunicata*) [126] See tunicates.

V

vascular plants (*Tracheophyta*) [25] Plants with xylem and phloem. Major groups include the lycophytes [74] and euphyllophytes.

vertebrates (*Vertebrata*) [44] The largest group of chordates [43], characterized by a rigid endoskeleton supported by the vertebral column and an anterior skull encasing a brain. Includes hagfishes [127], lampreys [128], and the jawed vertebrates [45], although some biologists exclude the hagfishes from this group. See *also* craniates.

W

water bears See tardigrades.

water lilies (*Nymphaeaceae*) [82] A group of aquatic, freshwater angiosperms [28] that are rooted in soil in shallow water, with round floating leaves and flowers that extend above the water’s surface. They are the sister-group to most of the remaining flowering plants, with the exception of the genus *Amborella* [81].

wet-nosed primates (*Strepsirrhini*) A group of primate mammals [134] that includes lemurs and lorises.

X

xenoturbellids (*Xenoturbellida*) Wormlike organisms that feed on or parasitize marine mollusks. Relationships uncertain; thought to be a sister group of either ambulacrarians [42] or bilaterians [35].

Y

“yeasts” Convenience term for several distantly related groups of unicellular fungi [30].

Z

“zygospore fungi” (*Zygomycota*, if monophyletic) [90] A convenience term for a probably

paraphyletic group of fungi [30] in which hyphae of differing mating types conjugate to form a zygosporangium.

APPENDIX B Making Sense of Data: A Statistics Primer

This appendix is designed help you understand the analysis of biological data in a statistical context. We outline major concepts involved in the collection and analysis of data, and we present basic statistical analyses that will help you interpret, understand, and complete the Work with the Data and Apply What You've Learned problems throughout this book. Understanding these concepts will also help you understand and interpret scientific studies in general. We present formulas for some common statistical tests as examples, but the main purpose of this appendix is to help you understand the purpose and reasoning behind these tests. Once you understand the basis of an analysis, you may wish to use one of many free, online websites for conducting the tests (such as <http://vassarstats.net>).

Why Do We Do Statistics?

ALMOST EVERYTHING VARIES We live in a variable world, but within the variation we see among biological organisms there are predictable patterns. We use statistics to find and analyze these patterns. Consider any group of common things in nature—all people aged 22, all the cells in your liver, or all the blades of grass in your yard. Although they will have many similar characteristics, they will also have important differences. Men aged 22 tend to be taller than women aged 22, but of course not every man will be taller than every woman in this age group.

Natural variation can make it difficult to find general patterns. For example, scientists have determined that smoking increases the risk of developing lung cancer. But we know that not all smokers will develop lung cancer and not all nonsmokers will remain cancer-free. If we compare just one smoker with just one nonsmoker, we may end up drawing the wrong conclusion. So how did scientists discover this general pattern? How many smokers and nonsmokers did they examine before they felt confident about the risk of smoking?

Statistics helps us find and describe general patterns in nature, and draw conclusions from those patterns.

AVOIDING FALSE POSITIVES AND FALSE NEGATIVES When a woman takes a pregnancy test, there is some chance that it will be positive even if she is not pregnant, and there is some chance that it will be negative even if she is pregnant. We call these kinds of mistakes “false positives” and “false negatives.”

Doing science is a bit like taking a medical test. We observe patterns in the world, and we try to draw conclusions about how the world works from those observations. Sometimes our observations lead us to draw the wrong conclusions. We might conclude that a phenomenon occurs, when it actually does not; or we might conclude that a phenomenon does not occur, when it actually does.

For example, planet Earth has been warming over the past century (see [Key Concept 57.4](#)). Ecologists are interested in whether plant and animal populations have been affected by global

warming. If we have long-term information about the locations of species and about temperatures in certain areas, we can determine whether shifts in species distributions coincide with temperature changes. Such information, however, can be very complicated. Without proper statistical methods, one may not be able to detect the true impact of temperature, or instead may think a pattern exists when it does not.

Statistics helps us avoid drawing the wrong conclusions.

How Does Statistics Help Us Understand the Natural World?

Statistics is essential to scientific discovery. Most biological studies involve five basic steps, each of which requires statistics:

Step 1: Choose an Experimental Design

Clearly define the scientific question and the methods necessary to tackle the question.

Step 2: Collect Data

Gather information about the natural world through observations and experiments.

Step 3: Organize and Visualize the Data

Use tables, graphs, and other useful representations to gain intuition about the data.

Step 4: Summarize the Data

Summarize the data with a few key statistical calculations.

Step 5: Make Inferences from the Data

Use statistical methods to draw general conclusions from the data about the world and the ways it works.

Step 1: Choose an Experimental Design

We make observations and conduct experiments to gain knowledge about the world. Scientists come up with scientific ideas based on prior research and their own observations. These ideas start as a question such as “Does smoking cause cancer?” From prior experience, scientists then propose possible answers to the question in the form of hypotheses such as “Smoking increases the risk of cancer.” Experimental design then involves devising comparisons that can test predictions of the hypotheses. For example, if we are interested in evaluating the hypothesis that smoking increases cancer risk, we might decide to compare the incidence of cancer in nonsmokers and smokers. Our hypothesis would predict that the cancer incidence is higher in smokers than in nonsmokers. There are various ways we could make that comparison. We could compare the smoking history of people newly diagnosed with cancer with that of people whose tests came out negative for cancer. Alternatively, we could assess the current smoking habits of a sample of people and see whether those who smoke more heavily are more likely to develop cancer in, say, 5 years. Statistics provides us with tools for assessing which approach will provide us with an answer with smaller costs in time and effort in data collection and analysis.

We use statistics to guide us in planning exactly how to make our comparisons—what kinds of data and how many observations we will need to collect.

Step 2: Collect Data

TAKING SAMPLES When biologists gather information about the natural world, they typically

collect representative pieces of information, called **data** or observations. For example, when evaluating the efficacy of a candidate drug for medulloblastoma brain cancer, scientists may test the drug on tens or hundreds of patients, and then draw conclusions about its efficacy for all patients with these tumors. Similarly, scientists studying the relationship between body weight and clutch size (number of eggs) for female spiders of a particular species may examine tens to hundreds of spiders to make their conclusions.

We use the expression “sampling from a population” to describe this general method of taking representative pieces of information from the system under investigation (**Figure B1**). The pieces of information together make up a **sample** of the larger system, or **population**. In the cancer therapy example, each observation was the change in a patient’s tumor size 6 months after initiating treatment, and the population of interest was all individuals with medulloblastoma tumors. In the spider example, each observation was a pair of measurements—body weight and clutch size—for a single female spider, and the population of interest was all female spiders of this species.

Figure B1 Sampling from a Population Biologists take representative samples from a population, use descriptive statistics to characterize their samples, and then use inferential statistics to draw conclusions about the original population.

Sampling is a matter of necessity, not laziness. We cannot hope (and would not want) to collect and weigh *all* of the female spiders of the species of interest on Earth! Instead, we use statistics to determine how many spiders we must collect to confidently infer something about the general population and then use statistics again to make such inferences.

DATA COME IN ALL SHAPES AND SIZES

In statistics we use the word “variable” to mean a measurable characteristic of an individual component of a system. Some variables are on a numerical scale, such as the daily high temperature or the clutch size of a spider. We call these **quantitative variables**. Quantitative variables that take on only whole number values (such as spider clutch size) are called **discrete variables**, whereas variables that can also take on a fractional value (such as temperature) are called **continuous variables**.

Other variables take categories as values, such as a human blood type (A, B, AB, or O) or an ant caste (queen, worker, or male). We call these **categorical variables**. Categorical variables with a natural ordering, such as a final grade in Introductory Biology (A, B, C, D, or F), are called **ordinal variables**.

Each class of variables comes with its own set of statistical methods. We will introduce a few common methods in this appendix that will help you work on the problems presented in this book, but you should consult a biostatistics textbook for more advanced tests and analyses for other data sets and problems.

Step 3: Organize and Visualize the Data

Your data consist of a series of values of the variable or variables of interest, each from a separate observation. For example, **Table B1** shows the weight and length of 34 fish (*Abramis brama*) from Lake Laengelmavesi in Finland. From this list of numbers, it’s hard to get a sense of how big the fish in the lake are, or how variable they are in size. It’s much easier to gain

intuition about your data if you organize them. One way to do this is to group (or bin) your data into **classes**, and count up the number of observations that fall into each class. The result is a **frequency distribution**. **Table B2** shows the fish weight data as a frequency distribution. For each 100-gram weight class, Table B2 shows the number, or frequency, of observations in that weight class, as well as the relative frequency (proportion of the total) of observations in that weight class. Notice that the data take up much less space when organized in this fashion. Also notice that we can now see that most of the fish fall in the middle of the weight range, with relatively few very small or very large fish.

table B1 Weight and Length Measurements for a Sample of *Abramis brama* from Lake Laengelmavesi

Individual number	Fish weight (g)	Fish length (cm)
1	242	30.0
2	290	31.2
3	340	31.1
4	363	33.5
5	390	35.0
6	430	34.0
7	450	34.7
8	450	35.1
9	475	36.2
10	500	34.5
11	500	36.2
12	500	36.2
13	500	36.4
14	575	38.7
15	600	37.3
16	600	37.2
17	610	38.5
18	620	39.2
19	650	38.6
20	680	39.7
21	685	39.5
22	700	37.2
23	700	38.3
24	700	40.6
25	714	40.6
26	720	40.9
27	725	40.5
28	850	41.5
29	920	42.6
30	925	44.0
31	950	45.9
32	955	44.1
33	975	45.3
34	1,000	41.6

table B2 Summary of Fish Weights of *Abramis brama* from Lake Laengelmavesi

Weight (g)	Frequency	Relative frequency
201-300	2	0.06
301-400	3	0.09
401-500	8	0.24
501-600	3	0.09
601-700	8	0.24
701-800	3	0.09
801-900	1	0.03

901-1,000	6	0.18
Total	34	1.0

Media Clip B1 Interpreting Frequency Distributions www.Life11e.com/mcB1

It is even easier to visualize the frequency distribution of fish weights if we graph them in the form of a **histogram** such as the one in **Figure B2**. When grouping quantitative data, it is necessary to decide how many classes to include. It is often useful to look at multiple histograms before deciding which grouping offers the best representation of the data.

Figure B2 Histograms Depict Frequency Distributions of Quantitative Data This histogram shows the relative frequency of different weight classes of fish (*Abramis brama*).

Frequency distributions are also useful ways of summarizing categorical data. **Table B3** shows a frequency distribution of the colors of 182 poinsettia plants (red, pink, or white) resulting from an experimental cross between two parent plants. Notice that, as with the fish example, the table is a much more compact way to present the data than a list of 182 color observations would be. For categorical data, the possible values of the variable are the categories themselves, and the frequencies are the number of observations in each category. We can visualize frequency distributions of categorical data like this by constructing a **bar chart**. The heights of the bars indicate the number of observations in each category (**Figure B3**). Another way to display the same data is in a **pie chart**, which shows the proportion of each category represented like pieces of a pie (**Figure B4**).

table B3 poinsettia Colors

Color	Frequency	Proportion
Red	108	0.59
Pink	34	0.19
White	40	0.22
Total	182	1.0

Figure B3 Bar Charts Compare Categorical Data This bar chart shows the frequency of three poinsettia colors that result from an experimental cross.

Figure B4 Pie Charts Show Proportions of Categories This pie chart shows the proportions of the three poinsettia colors presented in Table B3.

Sometimes we wish to compare two quantitative variables. For example, the researchers at Lake Laengelmavesi investigated the relationship between fish weight and length, from the data presented in Table B1. We can visualize this relationship using a [scatter plot](#), in which the combination of the weight and length of each fish is represented as a single point (**Figure B5**). These two variables have a [positive relationship](#) since the slope of a line drawn through the points is positive. As the length of a fish increases, its weight tends to increase in an approximately linear manner.

Figure B5 Scatter Plots Contrast Two Variables Scatter plot of *Abramis brama* weights and lengths (measured from nose to end of tail). These two variables have a positive relationship since the slope of a line drawn through the points is positive.

Tables and graphs are critical to interpreting and communicating data, and thus should be as self-contained and understandable as possible. Their content should be easily understood simply by looking at them. Axes, captions, and units should be clearly labeled, statistical terms should be defined, and appropriate groupings should be used when tabulating or graphing quantitative data.

Step 4: Summarize the Data

A **statistic** is a numerical quantity calculated from data, whereas **descriptive statistics** are quantities that describe general patterns in data. Descriptive statistics allow us to make straightforward comparisons among different data sets and concisely communicate basic features of our data.

DESCRIBING CATEGORICAL DATA For categorical variables, we typically use proportions to describe our data. That is, we construct tables containing the proportions of observations in each category. For example, the third column in Table B3 provides the proportions of poinsettia plants in each color category, and the pie chart in Figure B4 provides a visual representation of those proportions.

DESCRIBING QUANTITATIVE DATA For quantitative data, we often start by calculating **measures of center**, quantities that roughly tell us where the center of our data lies. There are three commonly used measures of center:

The **mean**, or average value, of our sample is simply the sum of all the values in the sample divided by the number of observations in our sample (**Figure B6**).

The **median** is the value at which there are equal numbers of smaller and larger observations.

The **mode** is the most frequent value in the sample.

FIGURE B6 Descriptive Statistics for Quantitative Data

Below are the equations used to calculate the descriptive statistics we discuss in this appendix. You can calculate these statistics yourself, or use free internet resources to help you make your calculations.

Notation:

$x_1, x_2, x_3, \dots, x_n$ are the n observations of variable X in the sample.

$\sum_{i=1}^n x_i = x_1 + x_2 + x_3 + \dots + x_n$ is the sum of all of the observations.
(The Greek letter sigma, Σ , is used to denote "sum of.")

In regression, the independent variable is X , and the dependent variable is Y . b_0 is the vertical intercept of a regression line.
 b_1 is the slope of a regression line.

Equations

1. Mean: $\bar{x} = \frac{\sum_{i=1}^n x_i}{n}$

2. Standard deviation: $s = \sqrt{\frac{\sum (x_i - \bar{x})^2}{n-1}}$

3. Correlation coefficient: $r = \frac{\sum (x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum (x_i - \bar{x})^2 \sum (y_i - \bar{y})^2}}$

4. Least-squares regression line: $Y = b_0 + b_1X$

where $b_1 = \frac{\sum (x_i - \bar{x})(y_i - \bar{y})}{\sum (x_i - \bar{x})^2}$ and $b_0 = \bar{y} - b_1\bar{x}$

5. Standard error of the mean: $x_s^2 = \sum \frac{(O_i - \bar{O})^2}{i}$

It is often just as important to quantify the variation in the data as it is to calculate its center. There are several statistics that tell us how much the values differ from one another. We call these **measures of dispersion**. The easiest one to understand and calculate is the **range**, which is simply the largest value in the sample minus the smallest value. The most commonly used measure of dispersion is the **standard deviation**, which calculates the extent to which the data are spread out from the mean. A deviation is the difference between an observation and the mean of the sample. The standard deviation is a measure of how far the average observation in the sample is from the sample mean. Two samples can have the same range, but very different standard deviations if observations in one are clustered closer to the mean than in the other. In **Figure B7**, for example, sample 1 has a smaller standard deviation than does sample 2, even though the two samples have the same means and ranges.

Figure B7 Measures of Dispersion Two samples with the same mean (black horizontal lines) and range. Red lines show the deviations of each observation from the mean. Samples with large deviations have large standard deviations. Sample 1 has a smaller standard deviation than sample 2.

To demonstrate these descriptive statistics, let's return to the Lake Laengelmavesi study (see the data in Table B1). The mean weight of the 34 fish (see equation 1 in Figure B6) is:

$$\bar{X} = \frac{\text{sum of the weight of all fish in sample}}{\text{number of fish in sample}} = \frac{21,284 \text{ g}}{34} = 626 \text{ g}$$

Since there is an even number of observations in the sample, then the median weight is the value halfway between the two middle values:

$$\frac{610 \text{ g} + 620 \text{ g}}{2} = 615 \text{ g}$$

The mode of the sample is 500 g, which appears four times. The standard deviation (see equation 2 in Figure B6) is:

$$s = \sqrt{\frac{\sum (X - \bar{X})^2}{n-1}} = 206.6 \text{ g}$$

and the range is 1,000 g – 242 g = 758 g.

DESCRIBING THE RELATIONSHIP BETWEEN TWO QUANTITATIVE VARIABLES Biologists are often interested in understanding the relationship between two different quantitative variables: How does the height of an organism relate to its weight? How does air pollution relate to the prevalence of asthma? How does lichen abundance relate to levels of air pollution? Recall that scatter plots visually represent such relationships.

We can quantify the strength of the relationship between two quantitative variables using a single value called the Pearson product-moment **correlation coefficient** (see equation 3 in Figure B6). This statistic ranges between -1 and 1 and tells us how closely the points in a scatter plot conform to a straight line. A negative correlation coefficient indicates that one variable decreases as the other increases; a positive correlation coefficient indicates that the two variables increase together; and a correlation coefficient of zero indicates that there is no linear relationship between the two variables (**Figure B8**).

Figure B8 Correlation Coefficients The correlation coefficient (r) indicates both the strength and the direction of the relationship.

One must always keep in mind that *correlation does not mean causation*. Two variables can be closely related without one causing the other. For example, the number of cavities in a child's mouth correlates positively with the size of his or her feet. Clearly cavities do not enhance foot growth; nor does foot growth cause tooth decay. Instead the correlation exists because both quantities tend to increase with age.

Intuitively, the straight line that tracks the cluster of points on a scatter plot tells us something about the typical relationship between the two variables. Statisticians do not, however, simply eyeball the data and draw a line by hand. They often use a method called least-squares **linear regression** to fit a straight line to the data (see equation 4 in Figure B6). This method calculates the line that minimizes the overall vertical distances between the points in the scatter plot and the line itself. These distances are called **residuals** (Figure B9). Two parameters describe the regression line: b_0 (the vertical intercept of the line, or the expected value of variable Y when $X = 0$), and b_1 (the slope of the line, or how much values of Y are expected to change with changes in values of X).

Figure B9 Linear Regression Estimates the Typical Relationship between Two Variables Least-squares linear regression line for *Abramis brama* weights and lengths (measured from nose to end of tail). The regression line is given by the equation $Y = 26.1 + 0.02X$. It is the line that minimizes the sum of the squares of the residuals.

Step 5: Make Inferences from the Data

Data analysis often culminates with statistical inference—an attempt to draw general conclusions about the system under investigation—the larger population—from observations of a representative sample (see Figure B1). When we test a new medulloblastoma brain cancer drug on ten patients, we do not simply want to know the fate of those ten individuals; rather, we

hope to predict the drug’s efficacy on the much larger population of all medulloblastoma patients.

STATISTICAL HYPOTHESES Once we have collected our data, we want to evaluate whether or not they fit the predictions of our hypothesis. For example, we want to know whether or not cancer incidence is greater in our sample of smokers than in our sample of nonsmokers, whether or not clutch size increases with spider body weight in our sample of spiders, or whether or not growth of a sample of fertilized plants is greater than that of a sample of unfertilized plants.

Before making statistical inferences from data, we must formalize our “whether or not” question into a pair of opposing hypotheses. We start with the “or not” hypothesis, which we call the **null hypothesis** (denoted H_0) because it often is the hypothesis that there is no difference between sample means, no correlation between variables in the sample, or no difference between our sample and an expected frequency distribution. The **alternative hypothesis** (denoted H_A) is that there is a difference in means, that there is a correlation between variables, or that the sample distribution does differ from the expected one.

Suppose, for example, we would like to know whether or not a new vaccine is more effective than an existing vaccine at immunizing children against influenza. We have measured flu incidence in a group of children who received the new vaccine and want to compare it with flu incidence in a group of children who received the old vaccine. Our statistical hypotheses would be as follows:

- H_0 : Flu incidence was the same in both groups of children.
- H_A : Flu incidence was different between the two groups of children.

In the next few sections we will discuss how we decide when to reject the null hypothesis in favor of the alternative hypothesis.

JUMPING TO THE WRONG CONCLUSIONS There are two ways that a statistical test can go wrong (**Figure B10**). We can reject the null hypothesis when it is actually true (**Type I error**), or we can accept the null hypothesis when it is actually false (**Type II error**). These kinds of errors are analogous to false positives and false negatives in medical testing, respectively. If we mistakenly reject the null hypothesis when it is actually true, then we falsely endorse the incorrect hypothesis. If we are unable to reject the null hypothesis when it is actually false, then we fail to realize a yet undiscovered truth.

Our conclusion	The real world	
	Null hypothesis true (not more females)	Null hypothesis false (more females)
Null hypothesis true (not more females)	✓	Type II error (false negative)
Null hypothesis false (more females)	Type I error (false positive)	✓

Figure B10 Two Types of Errors Possible outcomes of a statistical test. Statistical inference can result in correct and incorrect conclusions about the population of interest.

Suppose we would like to know whether there are more females than males in a population of 10,000 individuals. To determine the makeup of the population, we choose 20 individuals randomly and record their sex. Our null hypothesis is that there are not more females than males; and our alternative hypothesis is that there are. The following scenarios illustrate the possible mistakes we might make:

Scenario 1: The population actually has 40% females and 60% males. Although our random sample of 20 people is likely to be dominated by males, it is certainly possible that, by chance, we will end up choosing more females than males. If this occurs, and we mistakenly reject the null hypothesis (that there are not more females than males), then we make a Type I error.

Scenario 2: The population actually has 60% females and 40% males. If, by chance, we end up with a majority of males in our sample and thus fail to reject the null hypothesis, then we make a Type II error.

Fortunately, statistics has been developed precisely to avoid these kinds of errors and inform us about the reliability of our conclusions.

The methods are based on calculating the probabilities of different possible outcomes. Although you may have heard or even used the word “probability” on multiple occasions, it is important that you understand its mathematical meaning. A **probability** is a numerical quantity that expresses the likelihood of some event. It ranges between zero and 1; zero means there is no chance the event will occur, and 1 means the event is guaranteed to occur. This only makes sense if there is an element of chance, that is, if it is possible the event will occur and possible that it will not occur. For example, when we flip a fair coin, it will land on heads with probability 0.5 and land on tails with probability 0.5. When we select individuals randomly from a population with 60% females and 40% males, we will encounter a female with probability 0.6 and a male with probability 0.4.

Probability plays a very important role in statistics. To draw conclusions about the real world (the population) from our sample, we first calculate the probability of obtaining our sample if the null hypothesis is true. Specifically, statistical inference is based on answering the following question:

Suppose the null hypothesis is true. What is the probability that a random sample would, by chance, differ from the null hypothesis as much as our sample differs from the null hypothesis?

If our sample is highly improbable under the null hypothesis, then we rule it out in favor of our alternative hypothesis. If, instead, our sample has a reasonable probability of occurring under the null hypothesis, then we conclude that our data are consistent with the null hypothesis and we do not reject it.

Returning to the sex ratio example, let's consider two new scenarios:

Scenario 3: Suppose we want to infer whether or not females constitute the majority of the population (our alternative hypothesis) based on a random sample containing 12 females and 8 males. We would calculate the probability that a random sample of 20 people includes at least 12 females assuming that the population, in fact, has a 50:50 sex ratio (our null hypothesis). This probability is 0.13, which is too high to rule out the null hypothesis.

Scenario 4: Suppose now that our sample contains 17 females and 3 males. If our population is truly evenly divided, then this sample is much less likely than the sample in scenario 3. The probability of such an extreme sample is 0.0002, and would lead us to rule out the null hypothesis and conclude that there are more females than males.

This agrees with our intuition. When choosing 20 people randomly from an evenly divided population, we would be surprised if almost all of them were female, but would not be surprised at all if we ended up with a few more females than males (or a few more males than females). Exactly how many females do we need in our sample before we can confidently infer that they make up the majority of the population? And how confident are we when we reach that conclusion? Statistics allows us to answer these questions precisely.

STATISTICAL SIGNIFICANCE: AVOIDING FALSE POSITIVES

Whenever we test hypotheses, we calculate the probability just discussed, and refer to this value as the **P-value** of our test. Specifically, the *P*-value is the probability of getting data as extreme as our data (just by chance) if the null hypothesis is in fact true. In other words, it is the likelihood that chance alone would produce data that differ from the null hypothesis as much as our data differ from the null hypothesis. How we measure the difference between our data and the null hypothesis depends on the kind of data in our sample (categorical or quantitative) and the nature of the null hypothesis (assertions about proportions, single variables, multiple variables, differences between variables, correlations between variables, etc.).

For many statistical tests, *P*-values can be calculated mathematically. One option is to quantify the extent to which the data depart from the null hypothesis and then use look-up tables (available in most statistics textbooks or on the internet) to find the probability that chance alone would produce a difference of that magnitude. Most scientists, however, find *P*-values primarily by using statistical software rather than hand calculations combined with look-up tables. Regardless of the technology, the most important steps of the statistical analysis are still left to the researcher: constructing appropriate null and alternative hypotheses, choosing the correct statistical test, and drawing correct conclusions.

After we calculate a *P*-value from our data, we have to decide whether it is small enough to conclude that our data are inconsistent with the null hypothesis. This is decided by comparing the *P*-value to a threshold called the **significance level**, which is often chosen even before making any calculations. We reject the null hypothesis only when the *P*-value is less than or equal to the significance level, denoted α . This ensures that, if the null hypothesis is true, we have at most a probability β of accidentally rejecting it. Therefore the lower the value of α , the less likely we are to make a Type I error (see the lower left cell of Figure B10). The most commonly used significance level is $\alpha = 0.05$, which limits the probability of a Type I error to 5%.

If our statistical test yields a *P*-value that is less than our significance level α , then we conclude that the effect described by our alternative hypothesis is statistically significant at the level α and we reject the null hypothesis. If our *P*-value is greater than α , then we conclude that we are unable to reject the null hypothesis. In this case, we do not actually reject the alternative hypothesis, rather we conclude that we do not yet have enough evidence to support it.

POWER: AVOIDING FALSE NEGATIVES

The **power** of a statistical test is the probability that we will correctly reject the null hypothesis when it is false (see the lower right cell of Figure B10). Therefore the higher the power of the test, the less likely we are to make a Type II error (see the upper right cell of Figure B10). The power of a test can be calculated, and such calculations can be used to improve your methodology. Generally, there are several steps that can be taken to increase power and thereby avoid false negatives:

Decrease the significance level, α The higher the value of α the harder it is to reject the null hypothesis, even if it is actually false.

Increase the sample size. The more data one has, the more likely one is to find evidence against the null hypothesis, if it is actually false.

Decrease variability in the sample. The more variation there is in the sample, the harder it is to discern a clear effect (the alternative hypothesis) when it actually exists.

It is always a good idea to design your experiment to reduce any variability that may obscure the pattern you seek to detect. For example, it is possible that the chance of a child contracting influenza varies depending on whether he or she lives in a crowded (e.g., urban) environment or one that is less so (e.g., rural). To reduce variability, a scientist might choose to test a new influenza vaccine only on children from one environment or the other. After you have minimized such extraneous variation, you can use power calculations to choose the right combination of α

and sample size to reduce the risks of Type I and Type II errors to desirable levels.

There is a trade-off between Type I and Type II errors: as α increases, the risk of a Type I error decreases but the risk of a Type II error increases. As discussed above, scientists tend to be more concerned about Type I than Type II errors. That is, they believe it is worse to mistakenly believe a false hypothesis than it is to fail to make a new discovery. Thus they prefer to use low values of α . However, there are many real-world scenarios in which it would be worse to make a Type II error than a Type I error. For example, suppose a new cold medication is being tested for dangerous (life-threatening) side effects. The null hypothesis is that there are no such side effects. A Type II error might lead regulatory agencies to approve a harmful medication that could cost human lives. In contrast, a Type I error would simply mean one less cold medication among the many that already line pharmacy shelves. In such cases, policymakers take steps to avoid a Type II error, even if, in doing so, they increase the risk of a Type I error.

STATISTICAL INFERENCE WITH QUANTITATIVE DATA

Statistics that describe patterns in our samples are used to estimate properties of the larger population. Earlier we calculated the mean weight of a sample of *Abramis brama* in Lake Laengelmavesi, which provided us with an estimate of the mean weight of all the *Abramis brama* in the lake. But how close is our estimate to the true value in the larger population? Our estimate from the sample is unlikely to exactly equal the true population value. For example, our sample of *Abramis brama* may, by chance, have included an excess of large individuals. In this case, our sample would overestimate the true mean weight of fish in the population.

The **standard error** of a sample statistic (such as the mean) is a measure of how close it is likely to be to the true population value. The **standard error of the mean**, for example, provides an estimate of how far we might expect a sample mean to deviate from the true population mean. It is a function of how much individual observations vary within samples (the standard deviation) and the size of the sample (n). Standard errors increase with the degree of variation within samples, and they decrease with the number of observations in a sample (because large samples provide better estimates about the underlying population than do small samples). For our sample of 34 *Abramis brama*, we would calculate the standard error of the mean using equation 5 in Figure B6:

$$SE_{\bar{X}} = \frac{s}{\sqrt{n}} = \frac{206.6 \text{ g}}{\sqrt{34}} = 35.4 \text{ g}$$

The standard error of a statistic is related to the **confidence interval**—a range around the sample statistic that has a specified probability of including the true population value. The formula we use to calculate confidence intervals depends on the characteristics of the data, and the particular statistic. For many types of continuous data, the bounds of the **95% confidence interval** of the mean can be calculated by taking the mean and adding and subtracting 1.96 times the standard error of the mean. Consider our sample of 34 *Abramis brama*, for example. We would say that the mean of 626 g has a 95% confidence interval from 556.6 g to 695.4 g ($626 \pm 69.4 \text{ g}$). If all our assumptions about our data have been met, we would expect the true population mean to fall in this confidence interval 95% of the time.

Researchers typically use graphs or tables to report sample statistics (such as the mean) as well as some measure of confidence in them (such as their standard error or a confidence interval). This book is full of examples. If you understand the concepts of sample statistics, standard errors, and confidence intervals, you can see for yourself the major patterns in the data, without waiting for the authors to tell you what they are. For example, if samples from two groups have 95% confidence intervals of the mean that do not overlap, then you can conclude that it is unlikely that the groups have the same true mean.

Biologists conduct statistical tests to obtain more precise estimates of the probability of observing a given difference between samples if the null hypothesis that there is no difference in the populations is true. The appropriate test depends on the nature of the data and the experimental design. For example, we might want to calculate the probability that the mean weights of two different fish species in Lake Laengelmavesi, *Abramis brama* and *Leusiscus idus*, are the same. A simple method for comparing the means of two groups is the *t*-test, described in **Figure B11**. We looked earlier at data for *Abramis brama*; the researchers who collected these data also collected weights for six individuals of *Leusiscus idus*: 270, 270, 306, 540, 800, and 1,000 g. We begin by stating our hypotheses and choosing a significance level:

▶
research tools

Figure B11 The t-test What is the *t*-test? It is a standard method for assessing whether the means of two groups are statistically different from each other.

Step 1: State the null and alternative *hypotheses*:

H_0 : The two populations have the same mean.
 H_A : The two populations have different means.

Step 2: Choose a significance level, α , to limit the risk of a Type I error.

Step 3: Calculate the *test statistic*:
$$t_s = \frac{\bar{y}_1 - \bar{y}_2}{\sqrt{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}}}$$

Notation: y_1 and y_2 are the sample means; s_1 and s_2 are the sample standard deviations; and n_1 and n_2 are the sample sizes.

Step 4: Use the test statistic to assess whether the data are consistent with the null hypothesis:

Calculate the *P-value* (P) using statistical software or by hand using statistical tables.

Step 5: Draw conclusions from the test:

If $P \leq \alpha$, then reject H_0 , and conclude that the population distribution is significantly different.

If $P > \alpha$, then we do not have sufficient evidence to conclude that the means differ.

H_0 : *Abramis brama* and *Leusiscus idus* have the same mean weight.

H_A : *Abramis brama* and *Leusiscus idus* have different mean weights.

$$\alpha = 0.05$$

The test statistic is calculated using the means, standard deviations, and sizes of the two samples:

$$t_s = \frac{626 - 531}{\sqrt{\frac{207^2}{34} + \frac{310^2}{6}}} = 0.724$$

$$t_s = \frac{626 - 531}{\sqrt{\frac{207^2}{34} + \frac{310^2}{6}}} = 0.724$$

We can use statistical software or one of the free statistical sites on the internet to find that the P -value for this result is $P = 0.497$. Since P is considerably greater than α , we fail to reject the null hypothesis and conclude that our study does not provide evidence that the two species have different mean weights.

You may want to consult an introductory statistics textbook to learn more about confidence intervals, t -tests, and other basic statistical tests for quantitative data.

STATISTICAL INFERENCE WITH CATEGORICAL DATA

With categorical data, we often wish to ask whether the frequencies of observations in different categories are consistent with a hypothesized frequency distribution. We can use a [chi-square goodness-of-fit](#) test to answer this question.

Figure B12 outlines the steps of a chi-square goodness-of-fit-test. As an example, consider the data described in Table B3. Many plant species have simple Mendelian genetic systems in which parent plants produce progeny with three different colors of flowers in a ratio of 2:1:1. However, a botanist believes that these particular poinsettia plants have a different genetic system that does not produce a 2:1:1 ratio of red, pink, and white plants. A chi-square goodness-of-fit test can be used to assess whether or not the data are consistent with this ratio, and thus whether or not this simple genetic explanation is valid. We start by stating our hypotheses and significance level:

FIGURE B12 The Chi-Square Goodness-of-Fit Test

What is the chi-square goodness-of-fit test? It is a standard method for assessing whether a sample came from a population with a specific distribution.

Step 1: State the null and alternative *hypotheses*:

H_0 : The population has the specified distribution.

H_A : The population does not have the specified distribution.

Step 2: Choose a significance level, α , to limit the risk of a Type I error.

Step 3: Determine the *observed frequency* and *expected frequency* for each category:

The observed frequency of a category is simply the number of observations in the sample of that type.

The expected frequency of a category is the probability of the category specified in H_0 multiplied by the overall sample size.

Step 4: Calculate the *test statistic*: $\chi_s^2 = \sum_{i=1}^C \frac{(O_i - E_i)^2}{E_i}$

Notation: C is the total number of categories, O_i is the observed frequency of category i , and E_i is the expected frequency of category i .

Step 5: Use the test statistic to assess whether the data are consistent with the null hypothesis:

Calculate the *P-value* (P) using statistical software or by hand using statistical tables.

Step 6: Draw conclusions from the test:

If $P \leq \alpha$, then reject H_0 , and conclude that the population distribution is significantly different than the distribution specified by H_0 .

If $P > \alpha$, then we do not have sufficient evidence to conclude that population has a different distribution.

H_0 : The progeny of this type of cross have the following probabilities of each flower color:

$$\Pr\{\text{Red}\} = 0.50, \Pr\{\text{Pink}\} = 0.25, \Pr\{\text{White}\} = 0.25$$

H_A : At least one of the probabilities of H_0 is incorrect.

$$\alpha = 0.05$$

We next use the probabilities in H_0 and the sample size to calculate the expected frequencies:

	Red	Pink	White
Observed	108	34	40
Expected	$(.50)(182) = 91$	$(.25)(182) = 45.5$	$(.25)(182) = 45.5$

Based on these quantities, we calculate the chi-square test statistic:

$$\chi^2 = \sum_{i=1}^C \frac{(O_i - E_i)^2}{E_i} = \frac{(108-91)^2}{91} + \frac{(34-45.5)^2}{45.5} + \frac{(40-45.5)^2}{45.5} = 6.747$$

$$\chi^2_s = \sum_{i=1}^C \frac{(O_i - E_i)^2}{E_i} = \frac{(108-91)^2}{91} + \frac{(34-45.5)^2}{45.5} + \frac{(40-45.5)^2}{45.5} = 6.747$$

We find the P -value for this result to be $P = 0.034$ using statistical software. Since P is less than α , we reject the null hypothesis and conclude that the botanist is likely correct: the plant color patterns are not explained by the simple Mendelian genetic model under consideration.

This introduction is meant to provide only a brief introduction to the concepts of statistical analysis, with a few example tests. **Figure B13** summarizes some of the commonly used statistical tests that you may encounter in biological studies.

Figure B13 Some Common Methods of Statistical Inference This flowchart shows some of the commonly used methods of statistical inference for different combinations of data. Detailed descriptions of these methods can be found in most introductory biostatistics textbooks.

APPENDIX C Some Measurements Used in Biology

Measures of	Unit	Equivalents	Metric → English conversion
Length	meter (m)	base unit	1 m = 39.37 inches = 3.28 feet = 1.196 yards
	kilometer (km)	1 km = 1000 (10^3) m	1 km = 0.62 miles
	centimeter (cm)	1 cm = 0.01 (10^{-2}) m	1 cm = 0.39 inches
	millimeter (mm)	1 mm = 0.1 cm = 10^{-3} m	1 mm = 0.039 inches
	micrometer (μm)	1 μm = 0.001 mm = 10^{-6} m	
	nanometer (nm)	1 nm = 0.001 μm = 10^{-9} m	
Area	square meter (m^2)	base unit	1 m^2 = 1.196 square yards
	hectare (ha)	1 ha = 10,000 m^2	1 ha = 2.47 acres
Volume	liter (L)	base unit	1 L = 1.06 quarts
	milliliter (mL)	1 mL = 0.001 L = 10^{-3} L	1 mL = 0.034 fluid ounces
	microliter (μL)	1 μL = 0.001 mL = 10^{-6} L	
Mass	gram (g)	base unit	1 g = 0.035 ounces
	kilogram (kg)	1 kg = 1000 g	1 kg = 2.20 pounds
	metric ton (mt)	1 mt = 1000 kg	1 mt = 2,200 pounds = 1.10 ton
	milligram (mg)	1 mg = 0.001 g = 10^{-3} g	
	microgram (μg)	1 μg = 0.001 mg = 10^{-6} g	
Temperature	degree Celsius ($^{\circ}\text{C}$)	base unit	$^{\circ}\text{C} = (^{\circ}\text{F} - 32)/1.8$ $0^{\circ}\text{C} = 32^{\circ}\text{F}$ (water freezes)

			100°C = 212°F (water boils)
			20°C = 68°F (“room temperature”)
			37°C = 98.6°F (human internal body temperature)
	Kelvin (K)*	$K = ^\circ C - 273$	0 K = -460°F
Energy	joule (J)		1 J $\approx$ 0.24 calorie = 0.00024 kilocalorie+

*0 K (-273°C) is “absolute zero,” a temperature at which molecular oscillations approach 0—that is, the point at which motion all but stops.

+A *calorie* is the amount of heat necessary to raise the temperature of 1 gram of water 1°C. The *kilocalorie*, or nutritionist’s calorie, is what we commonly think of as a calorie in terms of food.

ANSWERS TO ALL IN-CHAPTER QUESTIONS

Chapter 1

RECAP 1.1

1. The origin of photosynthesis resulted in a gradual build-up of oxygen in the Earth's atmosphere. Before the Earth had an oxygen-rich atmosphere, UV radiation on the Earth's surface was so intense that it killed any organisms on land; life could only survive if it was protected from UV radiation by water. But as O₂ accumulated in the atmosphere, O₂ molecules began reacting with one another to form ozone (O₃). A layer of ozone gradually built up in the high atmosphere, and by about 500 million years ago it was sufficient to block enough UV radiation that life could colonize land.
2. Among the list of common characteristics of life on Earth, there are some features that we might expect to be general to any origin of life (such as the need to extract energy from the environment and use it to do work), but other features that we expect to be unique to each origin of life. For example, although another origin of life might use a genetic information system of some kind, there is no reason that we would expect the details of how that system functioned to be the same. Another origin of life might well use something other than DNA, or use different nucleotides to make up DNA. Moreover, even if another origin of life used the same basic building blocks to make DNA, the genetic code that specified which combinations of nucleotides encode which amino acids in proteins would be expected to be different. Furthermore, it is unlikely that the same set of amino acids would be used to construct proteins. It is the commonalities of these details across life on Earth that allow us to conclude that all life on Earth has a single common origin.
3. Fish typically have eyes that are used for sight, and eyes obviously require light to function. In a normal surface population, any mutation that disrupts eye-sight would be strongly selected against, because fish with non-functional eyes would be at a disadvantage compared to fish with functional eyes. Such mutations occur, but they are quickly eliminated from a surface population through natural selection. But in a cave population, there is no selection for eyesight, so such mutations are not selected against, and would accumulate in a cave population. In the absence of selection for eye function, we would expect gradual loss of a complex structure like an eye. In fact, many species of cave organisms do gradually evolve eyelessness over time. But how do they compensate for the loss of sight? Usually, there is strong selection for other sensory systems that do not require light, such as cells that detect small vibrations, or chemical scents. The important point is that in the dark environment, selection conditions change, and some features are expected to be lost, and others gained, because different features are favored under natural selection in the new environment.
4. Biologists use quantitative measures of similarities and differences between specimens to establish the relatedness of different species. The more similar, the more likely they have a recent common ancestor and the more different, the more likely their common ancestor is more remote in evolutionary time. Knowledge about phylogenetic relationships is also obtained from the fossil record and more recently from genomic analysis.

RECAP 1.2

1. A hypothesis is a proposed explanation for an observation or a phenomenon. An experiment is a rigorous test of that proposed explanation.
2. In a controlled experiment, all variables are held constant while one variable is manipulated to determine its effect on the system being studied.
3. When questions involve systems in which variables cannot be controlled, which is the case with many questions in natural systems, a comparative approach can be used to establish correlations between the variable of interest and its possible effects.
4. Since all life is related through evolution, different species use similar molecular, biochemical, cellular, physiological, and even behavioral components, systems, and mechanisms. Therefore what is learned from one species is likely to be applicable to other species.

RECAP 1.3

1. Modern biology is used to improve agricultural species—both plants and animals. An example is the genetic improvements of the plants that produce food grains. Biology is also used to treat diseases in agricultural species (e.g., antibiotics given to food animals) and to yield food plants resistant to herbicides.
2. The use of antibiotics creates a situation of artificial selection analogous to natural selection. Any disease organism that survives the antibiotic because of its genetic makeup will transmit that trait to its offspring. As the antibiotic continues to be used, the disease organisms with the resistance trait will multiply, resulting in decreased efficacy of the drug.
3. The Investigating Life thread in this chapter makes evident that global warming presents an enormous threat to reef-building corals, which support a high level of diversity in the marine ecosystem. Another notable example is the plight of the polar bear, which depends on sea ice to be able hunt its prey—seals. With the decrease in sea ice in the Arctic, the hunting areas and therefore hunting abilities of the polar bear have become more and more limited.

FIGURE QUESTIONS

Figure 1.9 This tree shows that the last common ancestor for fungi and animals was much more recent than the last common ancestor for fungi and plants. Fungi are therefore more closely related to animals than to plants.

Figure 1.15 The data reveal that the eastern- and western-breeding populations of bluefin tuna share the same mid-Atlantic feeding ground. Since the western-breeding population is commonly found east of the boundary line, the imposition of restrictions west of the boundary line would not have been effective in protecting the western-breeding population.

WORK WITH THE DATA, P. 14

1.

2. For the cool-pool corals, the probability of $H_0 = (0.5)^{17} = 0.00000762939$. Therefore we can safely reject H_0 and conclude that there is indeed a significant effect of heat stress on coral bleaching (at $P < 0.00001$). In other words, if the null hypothesis were true and there were no real effect of heat stress on coral bleaching, we would expect to see this many chlorophyll ratios below 1.0 fewer than 1 time out of 100,000 trials. For the warm-pool corals, there are seven observed values < 1 , and none > 1 . In this case, the probability of $H_0 = (0.5)^7 = 0.0078125$. Therefore we can again reject H_0 and conclude that there is a significant effect of heat stress on coral bleaching in warm-pool corals as well (this time at $P < 0.01$).
3. The results of the randomization trials will differ depending on how well the cards are shuffled and how many replicates are compared, but the probability of finding a difference as great as 0.35 (the observed difference) in truly randomized samples of the two groups is very low ($P < 0.001$). Therefore we can again reject the null hypothesis and conclude that the effects of heat stress on coral bleaching are indeed higher in the corals from cool pools than in those from warm pools.
4. The different distributions of chlorophyll ratios for the cool- and warm-pool corals indicate that although both populations suffer bleaching as a consequence of heat stress, the populations from the cool pools are more sensitive. This suggests that corals from warmer environments might replace those from cooler environments under long-term conditions of global warming.

APPLY WHAT YOU'VE LEARNED

1. The results show that a population is more likely to go extinct if a deleterious environmental change is sudden and less likely to go extinct if the change is gradual. The complete loss of a species is more likely to happen if a deleterious change in the environment occurs rapidly and wipes out most of the populations of that species. Even if a few individuals survive, they may not be present in large enough

- numbers to effectively reproduce and maintain a viable population. However, if the environmental change is gradual, the population has time to allow surviving members to reproduce and enhance the proportion of individuals with the ability to survive, which allows the population to undergo adaptation to the change
2. The investigation shows how populations of living things evolve in response to changing environments. It models the process of natural selection that operates on populations and results in evolution. Environmental change and natural selection have helped shape the characteristics of organisms throughout the history of life on Earth.
 3. All living things on Earth arose from a common ancestor and share certain characteristics. For example, all living things contain DNA, which encodes the information that passes from generation to generation. DNA is affected by mutation, which produces variation within a population. All living things are also affected by natural selection, which results in adaptation of populations and species over time. Because all living things possess DNA and are affected by natural selection, the results of the investigation are expected to be broadly applicable to life.
 4. This was a controlled study because all of the cells were treated the same way (all variables were controlled) except for one condition that was varied. The varied condition was the amount of rifampicin added to the culture medium. (EXAMPLE) A comparative study could track changes in characteristics of a population of fish (or other species) cut in two by the building of a dam or other human-made construction. In a case like this, the study would have to show that the dam separated the original population into distinct groups that were isolated from each other and exposed to different environmental conditions. The study could then compare the characteristics of the separated groups of fish after a period of time to observe how the groups change in response to their respective environments
 5. Yes. The research organization could use the results of the investigation as an example to show that any population of bacteria likely has some proportion of individuals with genetic mutations that allow a degree of resistance to an antibiotic. Over time, selection for resistance will result in an increasing proportion of individual bacteria in that population that can grow in the presence of the antibiotic. Therefore, an antibiotic effective at killing bacteria does not remain effective over time as the bacterial populations evolve resistance to the antibiotic. This means that new antibiotics need to be developed periodically to take the place of older ones that lose their effectiveness as bacteria develop resistance to them. Using this reasoning, the research organization can show the need for a continuous pipeline of new antibiotics to deal with the problem of bacterial resistance.

Chapter 2

RECAP 2.1

1. Elements with the same number of valence electrons are placed in the same vertical groups in the periodic table. For example, the electrons in sodium occupy the following shells (in order from the nucleus outward): 1s², 2s², 2p⁶, 3s¹. Having one electron in the valence shell places sodium in Group 1. Lithium and potassium, which likewise have one electron in the valence shell, are in Group 1 as well.
2. An atom is stable when its eight electrons occupy its outermost shell (with the exception of hydrogen, which is stable with two electrons). In bonding, atoms either share electrons with, or donate to or receive electrons from, another atom to achieve stability.
3. The human body has the same elemental composition as Earth's crust but in very different proportions.

RECAP 2.2

1. In a covalent bond, the shared electrons between two atoms are actually part of both atoms. They are close together, and it takes a lot of energy to break them apart. In an ionic attraction, the electrons are transferred and the two atoms are relatively far apart, so it takes less energy to break an ionic attraction.
2. a. nonpolar; polar; polar; nonpolar;
b. hydrophobic; hydrophilic; hydrophilic; hydrophobic
c. C=O: δ⁻ at O; O—P: δ⁻ at O;
3. This is an example of van der Waals forces, which act over a short distance and do not involve polarity.

RECAP 2.3

1. $X \text{ C}_6\text{H}_{12}\text{O}_6 + X \text{ O}_2 \rightarrow X \text{ CO}_2 + X \text{ H}_2\text{O}$
2. In the burning of propane, there is a chemical transformation. Some chemical energy is released as heat and light.

RECAP 2.4

1. A solution contains a solvent (e.g., water) and a substance dissolved in the solvent (e.g., table salt, NaCl). Water is the medium of life because most molecules in living organisms either dissolve in water or interact with it.
2. A 1 molar (1 M) solution has a concentration of 1 mole per liter, which means it has 6.02×10^{23}

molecules per liter. A 10^{-8} M solution has 6.02×10^{15} molecules per liter. If there is 10^{-6} liters, the number of molecules is 6.02×10^9 .

3. This reaction increases the H^+ concentration in the blood and thereby decreases the pH. To increase the pH, and thereby decrease the H^+ , the reverse reaction could be used as a buffer:

WORK WITH THE DATA

1. The average local ratios differ from the all-countries average ratio. To test the hypothesis that the ratios are significantly different, a chi-square test could be used.
2. A graph of the data shows an increasing $^{13}C:^{12}C$ ratio as latitude away from the equator increases. This implies that different plants occur in different regions. Animal feeds used locally tend to be composed of plants grown locally.

FIGURE QUESTIONS

[Figure 2.3](#) The technique could be used to monitor therapy. As therapy progresses and the patient improves, one would expect that the brain region involved would show more activity.

[Figure 2.6](#)

Figure 2.8 Ca (atomic number 20) has two valence electrons. Cl (atomic number 17) has seven valence electrons. So combining, two electrons are lost from one Ca atom to two atoms of Cl: formula CaCl_2 .

Figure 2.9 At the chemical level, evaporation eliminates water for hydration of the ions, so the ions are no longer separated. At the physical level, the salt no longer dissolves and crystals form.

Figure 2.10 Heat will break hydrogen bonds. Because these bonds affect the interactions of some chemical groups with other groups at different locations in the molecule, the three-dimensional structure of the molecule will change.

APPLY WHAT YOU'VE LEARNED

1.

2. $\text{HCO}_3^- + \text{H}^+ \rightleftharpoons \text{H}_2\text{CO}_3$ $\text{HCO}_3^- + \text{H}^+ \rightleftharpoons \text{H}_2\text{CO}_3$

The pH would not change. As H^+ was added due to ionization of acetoacetic acid, it would push the equilibrium of the above reaction to the right, as shown below.

added H^+ reacts with HCO_3^- to shift equilibrium to the right

That is, bicarbonate ions would attach to the added H^+ , so the overall free H^+ would not change.

- Eventually the bicarbonate buffer system would be overwhelmed. It would no longer be able to take up the additional H^+ ions building up in the blood and shuttle them into carbonic acid. At that point, H^+ ions would accumulate, which would cause the blood pH to drop. The body would not be able to maintain a constant pH and its cells would be exposed to lower than normal pH conditions in the blood. In this case, the person would become severely ill because the cells would be exposed to an abnormal environment that then disrupts normal cell functions.
- Acetone does not contain an acidic hydrogen, so it would not be expected to affect any acid or base buffering systems in the blood.
- Four test possibilities are: insulin level (lower than normal), blood glucose level (elevated), blood pH (lower than normal), and bicarbonate level (lower than normal).

Chapter 3

RECAP 3.1

- Structural isomers have the same number of atoms, but they are arranged differently. *Cis-trans* isomers typically have two double-bonded carbon atoms, and each of the two carbons is covalently bonded to two different groups as well (e.g., to $-\text{H}$, $-\text{CH}_3$, or another attached group). When the two substituents are oriented in the same plane relative to the double bond, the isomers are *cis*. When the two groups are oriented in opposing directions, the isomers are *trans*. Optical isomers have carbon atoms with four different atoms or groups bonded to them, and this makes two mirror images possible.
- Mannose and galactose have the same atomic formula, $\text{C}_6\text{H}_{12}\text{O}_6$, but the arrangement of atoms is different. Compare carbons 2 and 4. These sugars have the hydroxyl ($-\text{OH}$) functional group. Its polarity helps the sugars dissolve in water. The $-\text{OH}$ group also can participate in bonding the sugar to other molecules through condensation reactions.
- $\text{H}-\text{A}-\text{OH} + \text{H}-\text{B}-\text{OH} \rightarrow \text{H}-\text{A}-\text{B}-\text{OH} + \text{H}_2\text{O}$
 $\text{H}-\text{A}-\text{B}-\text{OH} + \text{H}-\text{C}-\text{OH} \rightarrow \text{H}-\text{A}-\text{B}-\text{C}-\text{OH} + \text{H}_2\text{O}$

RECAP 3.2

- When one amino acid (such as lysine) is replaced by another, the primary structure of the protein is altered. The change could affect tertiary structure if the protein folds differently as a result of electrostatic attractions between charged amino acids ($+$ to $-$). In this example, a negatively charged amino acid (aspartic acid) has taken the place of a positively charged one (lysine), and this may prevent correct folding, particularly if a negatively charged amino acid elsewhere in the polypeptide chain is involved in folding (it is attracted to a $+$ amino acid). The same forces might be at work in the interaction of separate chains for quaternary structure.
- The observations support explanation "a." Glycine is small and nonpolar. Glutamic acid and arginine are

larger and polar (charged). Serine and alanine are small: the protein retains its shape. But serine is polar (it has -OH as its R group), and that does not affect the structure. Valine is larger and nonpolar, and this affects shape. So the issue is size.

3. See [Figure 3.10](#). Heat breaks hydrogen bonds and other weak interactions that maintain protein shape. Disulfide bonds also are required for normal protein shape. Styling and perms partially denature keratin, then renature the protein in a new shape. Your investigation might involve measuring keratin protein structure of hair before and after disrupting hydrogen bonds and disulfide bonds.

RECAP 3.3

1. Starch and glycogen have many carbon atoms bonded covalently to one another. These covalent bonds require energy for formation and release energy when broken.
2. The many hydrogen bonds between polysaccharide chains of cellulose hold them together, and the covalent bonds within the chains are strong individually.

RECAP 3.4

1. The phospholipids would aggregate, with the polar heads facing in and the tails facing out—the reverse of what happens in membranes. This would probably be aggregates, rather than a bilayer.
2. Fats are solid at room temperature and have single bonds (saturated) between fatty acid carbon atoms (saturated). Oils are liquid at room temperature and have double bonds between some fatty acid carbon atoms (unsaturated).

3. Steroids and some vitamins are classified as lipids because they are composed largely of carbon atoms linked together with substituent hydrogen atoms and are insoluble in water and soluble in nonpolar solvents.

WORK WITH THE DATA, [P. 44](#)

1. The genetically engineered silk was better than the native spider silk. It was thicker, required more force to break, and resisted strain better than native spider silk.
2. Fiber thickness is reported because it is one indicator of fiber strength.
3. The *t*-test could determine this.
4. Spider silk is stronger than Kevlar or steel and weighs less.

WORK WITH THE DATA, [P. 52](#)

1. Disulfide bonds began forming almost immediately after reoxidation began. Enzyme activity began appearing 100 minutes after reoxidation began. There are two reasons for the delay between the beginning of disulfide bond formation and the reappearance of enzyme activity. First, there are four disulfide bonds in the protein, all of which have to re-form before enzyme activity is restored. In other words, the first disulfide bonds to form aren't sufficient to restore activity, so there is a lag before activity reappears. Second, there are other chemical interactions, such as hydrogen bonding and hydrophobic interactions that occur after the protein has initially folded due to disulfide bond formation and which are also necessary for enzyme activity.
2. The absorption peak for the native protein was at about 278 nm; the peak for the reduced (denatured)

protein was at about 275 nm. Reoxidation resulted in a return to the native spectrum. Under the denaturation conditions of these experiments, as long as the primary structure of RNase A is retained, the proper environmental conditions will result in a return to the native structure and a fully functional molecule.

FIGURE QUESTIONS

Figure 3.7 Primary structure will be unaffected, because it is held together by strong covalent bonds.

Figure 3.9 Regions in lysozyme that face the outside (water) environment are hydrophilic, whereas those on the inside are generally hydrophobic.

Figure 3.12 Weak interactions shown within or between molecules require a relatively low amount of energy to break them apart.

Figure 3.14 Heat shock proteins protect cellular proteins from being denatured and possibly broken down. This can occur not only when proteins are exposed to heat, but in any chemical situation where their structure is altered (e.g., a change in pH).

APPLY WHAT YOU'VE LEARNED

1. The forces involved are noncovalent and involve mainly hydrophobic and van der Waals interactions, since the R groups tend to be hydrophobic groups (Val, Ile, Phe, Gly). The R groups of these amino acids could stick out from the insulin polypeptide backbone so as to interact with its target proteins to form these noncovalent interactions.
2. These amino acids are invariant across all vertebrate species shown in the table, suggesting that they are essential in maintaining insulin's biological activity.
3. Certain changes are allowed as long as the overall tertiary structure of the protein is not changed significantly. Only amino acids that are similar in structure and properties would be able to function in a similar way at any position.
4. Cysteine residues are likely to be essential because they form disulfide bridges, linking the two chains together and stabilizing the protein's tertiary structure. No other amino acid can fulfill this role. We could compare these amino acids across the same vertebrate species shown above to see whether any have other amino acids at the cysteine locations.

Chapter 4

RECAP 4.1

1. Purines contain two nitrogen-carbon rings, while pyrimidines have one ring. The double helix of DNA has uniform width because a purine on one strand is always opposite a pyrimidine on the other strand.
2. While DNA molecules are similar in diameter and configuration, their base sequences are different. Differences in base sequence provide the informational content of DNA.
3. The number of possible 25-unit sequences of four nucleotides is 425, a large number indeed. Because of internal base pairing of the single strand (as in RNA), many folded configurations are possible, which allows specific binding to target molecules.

RECAP 4.2

1. The presence of O₂ in the atmosphere produces an oxidizing condition that prevents the reduction reactions observed in the Miller-Urey experiment.
2. If microbes survived heat, the initial part of Pasteur's experiment might begin with microbes already present. They would grow in both the open and closed flasks. To get the results that Pasteur did, his flasks must not have contained such microbes. An answer for the proposed experiment on heat-stable microbes might be to inactivate them using reagents, such as mercaptoethanol, that destroy proteins.
3. A suggested experiment might be to dry the samples after the Miller-Urey experiment (allowing condensation reactions—polymerization) and then apply energy in the form of heat. This condition might have existed in volcanic rock on early Earth.

RECAP 4.3

1. A hallmark of living systems is the ability to reproduce, and this occurs from preexisting organisms. The instructions for producing an identical organism must be passed on to the offspring. This implies informational molecules. In living systems, chemical changes constantly occur, but in ordinary chemistry they are too slow to benefit the organism. So catalysts are needed to speed up the reactions.
2. A challenge in developing theories for the origin of life was the need for both a molecule that could carry information and a molecule that could act as a catalyst. Without either, life as we know it could not exist. That an informational molecule, RNA, could also act as a catalyst solved this challenge; ribozymes, also known as catalytic RNA or RNAzyme, are RNA molecules that are capable of catalyzing specific biochemical reactions.

3. Most catalysts in living systems are proteins. But the polymerization of amino acids into proteins that are catalytic must have happened before the protein catalysts were initially formed. Having an RNA, that perhaps was originally informational, act as the catalyst for protein formation solves this “chicken–egg” issue.

RECAP 4.4

1. The cell membrane forms a compartment in which the chemicals needed for the reactions of life can be concentrated. The membrane creates a suitable internal chemical environment for the organism that is distinct from that of the environment.
2. First, examine rocks that are more than 3 billion years old. Then look at slices of rocks under microscopes for objects that look like cells or chains of cells. Finally, chemically analyze the rocks for chemical signatures for life, such as a carbon isotope ratio resulting from photosynthesis.

WORK WITH THE DATA, P. 74

1. Plot the data. In both experiments with unheated soil, there was a modest time-dependent increase in ^{14}C -labeled gases. These data are consistent with living organisms converting the molecules supplied into gases. The amount of gas produced was small in comparison with lab-based experiments: average radioactivity was 10,000 cpm, while potential was 257,000 cpm. Efficiency of production of gases was $10,000/257,000 = 0.038 = 4\%$.

2. The graph of the data shows no increase in ^{14}C gases. Heat destroys hydrogen bonds in proteins and nucleic acids. Again, these data are consistent with living organisms having produced ^{14}C gases.

3. The data for hematite are similar to the data for Martian soil. So while the Martian soil data are consistent with life, they are also consistent with non-living soil components.

FIGURE QUESTIONS

Figure 4.3 If a folded RNA molecule were heated, hydrogen bonds between bases in the RNA would break and the molecule would assume a random shape, losing its specific shape.

Figure 4.4 Hydrogen bonds

Figure 4.5 There must be specific information in DNA sequences that signal their transcription. These specific sequences must bind to proteins that are involved in transcription.

APPLY WHAT YOU'VE LEARNED

1. The ratio of purines (A + G) to pyrimidines (C + T) is always one-to-one. This pattern is observed because of the double helix structure and base pairing between the two strands making up the double helix. There is always one purine on one strand and a pyrimidine that pairs with it on the complementary strand.

DNA	A	G	Purines	C	T	Pyrimidines	Ratio purines to pyrimidines
Herring sperm	27.8	22.2	50	22.6	27.5	50.1	1.00
Rat bone marrow	28.6	21.4	50	21.5	28.4	49.9	1.00
Human sperm	30.7	19.3	50	18.8	31.2	50	1.00
<i>E. coli</i>	26	24.9	50.9	25.2	23.9	49.1	1.04
Yeast	31.3	18.7	50	17.1	32.9	50	1.00

2. The ratio of purines (A + G) to pyrimidines (C + U) ranges from 0.87 to 1.24, with lots of variation in between. Therefore there is no constant pattern in this ratio in RNA across many species. This indicates that the number of purines and pyrimidines varies within an RNA strand, which we know to be single-stranded.

RNA	A	G	Purines	C	U	Pyrimidines	Ratio purines to pyrimidines
Rat liver	19.2	28.5	47.7	27.5	24.8	52.3	0.91
Carp muscle	16.4	34.4	50.8	31.1	18.1	49.2	1.03
Yeast	25.1	30.2	55.3	20.1	24.6	44.7	1.24
Rabbit liver	19.7	26.8	46.5	25.8	27.6	53.4	0.87
Cat brain	21.6	31.8	53.4	26.0	20.6	46.6	1.15

3. The difference in ratios of purines to pyrimidines in DNA and RNA across species highlights the double-stranded nature of DNA and the single-stranded nature of RNA. Only in the double-stranded structure would you have a constant ratio of purines to pyrimidines because they are paired in a one-to-one ratio. In single-stranded RNA, there is no requirement for pairing purines and pyrimidines, and the variability in their content reflects differences in the genetic sequences of the strands.

4. Only *E. coli* has about equal AT and GC content. Human sperm and yeast have more AT than GC content, and rat bone marrow and herring sperm have more GC than AT content.

DNA	A	G	C	T	A + T	G + C
Herring sperm	27.8	22.2	22.6	27.5	55.3	44.8
Rat bone marrow	28.6	21.4	21.5	28.4	57	42.9
Human sperm	30.7	19.3	18.8	31.2	61.9	38.1
<i>E. coli</i>	26.0	24.9	25.2	23.9	49.9	50.1
Yeast	31.3	18.7	17.1	32.9	64.2	35.8

5. Herring sperm and rat bone marrow cells have similar AT and GC content. Their genetic makeups are determined by the sequences of bases in DNA, so even though they have similar overall base content, they each have unique sequences of all bases—A, T, G, and C—that encode the genes within the DNA.

Chapter 5

RECAP 5.1

- 1. Life is continuous: the cell theory explains that this comes from cell continuity. Life is complex chemically: the cell theory states that this chemistry occurs within cells. Life evolves and changes over time: the cell theory states that evolution occurs in cells as they change genetically and pass on new characteristics to the next generation of cells.
- 2. The membranes that enclose cells and organelles create compartments. The cell membrane allows the chemical reactions of life to occur away from the surrounding environment; in particular, the cell membrane permits the internal environment to have a distinct composition and concentration. Organelles' membranes permit specialized functions and keep harmful substances away from the rest of the cell (cytoplasm).

RECAP 5.2

- 1. The cell wall is composed of a large complex of polysaccharides and peptides. It supports the cell and

gives it shape. The capsule is a slimy polysaccharide layer that encloses the cell walls of some prokaryotes and keep cells from drying out. It may be used to attach to other cells. The flagellum is composed of strands of a large protein called flagellin and is attached to the cell wall and membrane by a motor complex. It is used for cell movement.

2. The nucleoid consists of DNA and proteins. Cytoplasm contains all the other small and large molecules for life, dissolved or suspended in water.

RECAP 5.3

1. Prokaryotic cells are smaller than eukaryotic cells and lack organelles.
2. (a) Four membranes: two in the chloroplast and two in the mitochondrion. (b) Two membranes: the lysosomal membrane and the cell membrane (via vesicle; the molecules do not themselves cross any membranes). (c) No membranes: ribosomes do not have membranes. However, if the ribosomes were associated with the endo-plasmic reticulum (ER), the answer would be two membranes: one into the ER and another out of the ER.
3. Microtubules line the long axons of nerve cells, where they act as tracks for vesicles that carry substances down the neuron. Without microtubules, the contents of these vesicles cannot be delivered to their destination, which can result in nerve problems. Depolymerization of microtubules can interfere with cell divisions because microtubules are a key part of the mitotic spindle that is used to move chromosomes during cell division.
4. For a lysosomal enzyme, the pathway would be ribosome → interior of ER → Golgi apparatus → Golgi vesicles → lysosome.
5. For an extracellular protein (animal cell), the pathway would be ribosome → interior of ER → Golgi apparatus → Golgi vesicles → cell membrane → extracellular region.

RECAP 5.4

1. Initially, there is a digestion of molecules that attach the cell membrane to the extracellular matrix. Then enzymes are produced and secreted from the cell that digests the macromolecules of the extracellular matrix. The cell migrates by microfilaments.
2. A cell wall contains cellulose fibers which provide strong support yet allow a plant to have some flexibility to bend. The cell wall structure provides an extra barrier that helps protect the cell from infection, yet cell walls in some cells have pores that allow the flow of materials in and out of the cell.
3. Chemical analysis could identify a plant cell by the presence of cellulose in the extracellular matrix and an animal cell by the presence of collagen in the extracellular matrix. These two compounds are distinct to the two different types of cells.

RECAP 5.5

1. The cell membrane could fold inward and then pinch off, forming vesicles for the Golgi apparatus and flat sheets for the ER.
2. The endosymbiotic theory states that one cell engulfed another cell. Over time the engulfed cell lost some DNA and the ability to perform independently of the host cell. Thus the engulfed cell became dependent on the host cell for its survival.

WORK WITH THE DATA, P. 99

1. The tannins appear in the chloroplast thylakoids and then are transferred to the vacuole by vesicles that enclose the tannins.
2. The staining for chlorophyll and tannins is in the same place. Since chlorophyll is in the chloroplast, this is consistent with a chloroplast origin for tannins, as described in the answer to Question 1.
3. Staining and chemical analysis both showed tannins, as well as chlorophyll, in the lower fraction of organelles, so this is probably a chloroplast fraction that contains tannins.

WORK WITH THE DATA, P. 103

1. The reasoning behind these experiments was as follows: if microfilaments are essential for cell movement, movement should not occur in the presence of cytochalasin B; if microtubules are essential for cell movement, movement should not occur in colchicine; if cell movement requires the synthesis of new proteins, movement should not occur in cycloheximide; and if cell movement requires energy, movement should not occur in dinitrophenol. The latter three experiments were important controls to rule out involvement of the three processes involved. The cycloheximide + cytochalasin B and the dinitrophenol + cytochalasin B controls demonstrated that the drugs had independent effects on the cells.
2. The experiment with cytochalasin B implicated microfilaments in cell movement. The experiment with colchicine ruled out microtubules. The experiments with cycloheximide showed that new protein synthesis is not necessary for cell movement. The experiments with dinitrophenol showed that cell movement does not require new inputs of energy.

FIGURE QUESTIONS

Figure 5.9 Assembly of the ER from the nuclear envelope; transport between Golgi apparatus cisternae; transport from ER to Golgi apparatus; endocytosis; exocytosis; transport from Golgi apparatus to cell membrane

Figure 5.11 Cells with high energy requirements, such as muscle cells, would have a lot of mitochondria.

Figure 5.18 Nexin links cause cilia and flagella to bend when microtubule doublets try to slide past one another. Absence of nexin would result in reduced flagella and ciliary function. This is called immotile cilia syndrome.

APPLY WHAT YOU'VE LEARNED

- The results show that the protein begins its path in the endoplasmic reticulum, passes through the Golgi apparatus, and ends up in the cell membrane.
- An inhibitor of protein synthesis would have prevented the fusion protein from being synthesized. Very little fluorescence (if any) would have been observed, and no fluorescence would have been observed moving into the Golgi apparatus or cell membrane.

- The researchers would not have learned anything new because the cell fractionation method would have provided the same information about changes in subcellular locations of fluorescence over time. However, the results should have confirmed what was found using microscopy, which can provide additional weight of evidence for making claims about the path of the protein.
- The researchers would have to use two different fluorescent tags that glow with different colors (e.g., green and red) so they could be distinguished from each other. Then the equipment used to collect data could be tuned to each color, and data collected at each color simultaneously.
- As long as the two fluorescent tags on the different proteins can be distinguished from each other, they can be followed along different paths in the cell. The peroxi-dase would be expected to move from the ER to the Golgi apparatus to the peroxi-some, while the secretory protein would be expected to move from the ER to the Golgi apparatus to the extracellular fluid. The two proteins would be found in the same compartments only in the ER and Golgi apparatus and would part ways as they entered different final destinations.

Time (min)	Peroxidase				Secretory Protein			
	ER	Golgi apparatus	Peroxisome	Extracellular fluid	ER	Golgi apparatus	Peroxisome	Extracellular fluid
0	1.0	0.0	0.0	0.0	1.0	0.0	0.0	0.0
10	0.6	0.3	0.1	0.0	0.6	0.3	0.0	0.1

50	0.2	0.3	0.5	0.0	0.2	0.3	0.0	0.5
100	0.1	0.2	0.7	0.0	0.1	0.2	0.0	0.7

Chapter 6

RECAP 6.1

1. The hydrophilic “heads” of fatty acids are the polar ends, and the hydrophobic “tails” are the nonpolar ends. So the heads tend to associate with water molecules, and the tails away from water molecules. Placed in an aqueous environment, the fatty acids will arrange themselves so that their tails interact with one another while their heads face the water of the environment and cytoplasm, forming a bilayer.
2. An integral membrane protein is embedded in the phospholipid bilayer by hydrophobic interactions with the lipid interior. It must have amino acids with hydrophobic R groups to insert into the nonpolar fatty acid tail region of the membrane bilayer. A peripheral membrane protein lacks hydrophobic regions and does not interact with the hydrophobic core of the phospholipid bilayer. Instead it is usually bound to the membrane indirectly by interactions with integral membrane proteins or directly by interactions with lipid polar head groups.
3. Both freeze-fracturing and cell fusion experiments indicate that nonpolar membrane proteins are inserted into the hydrophobic interior of the lipid bilayer. Cell fusion experiments also show that the proteins can move in the plane of the membrane.
4. To measure membrane fluidity, label a small amount of a lipid or protein with a dye and allow it to incorporate into the membrane of a cancer cell and a noncancer cell. This may make a localized labeled spot on the cells. The localized region will be seen to diffuse over the cells over time. In the cancer cell, this rate of diffusion may be faster.

RECAP 6.2

1. Enzymes called glycosidases cut the bonds between carbohydrates and other molecules. Obtain cells that are bound together (e.g., sponges) and then separate them. Then treat the cells with glycosidases to remove carbohydrates. This should block cell recognition and adhesion.
2. Plasmodesmata are most similar to gap junctions, because both have a membrane-lined channel.

RECAP 6.3

1. The properties that affect diffusion across a membrane are size and mass (smaller is faster), electric charge (less polar is faster), and concentration gradient (the higher the gradient, the faster the rate of diffusion).
2. If blood is hypotonic, water will enter red blood cells, causing them to swell and perhaps burst. (This is called hemolytic anemia.)
3. The hydrophobic cell membrane lipids are relatively impermeable to charged ions such as K^+ . A channel will allow diffusion of K^+ out of the cell until equilibrium is reached, with equal concentrations inside and outside the cell.

RECAP 6.4

1. Substances tend to diffuse and reach equilibrium, where they are evenly distributed in the environment. Energy is needed to overcome this natural tendency.
2. An antiporter transports two substances in opposite directions. In the case of the Na^+-K^+ pump, Na^+ is transported across the cell membrane outward, and K^+ is transported across the cell membrane inward.
3. In primary active transport, ATP hydrolysis supplies the energy needed for transport against a concentration gradient. In secondary active transport, the energy comes from a gradient set up by a different (secondary) active transport.
4. Both active transport and facilitated diffusion speed up transport across a membrane by using a protein that binds to the substance transported. However, active transport is an energy-requiring process that transports a substance against its concentration gradient and diffusion tendency. By contrast, facilitated diffusion does not require energy and transports a substance along its concentration gradient and in conjunction with its tendency to diffuse.

RECAP 6.5

1. Phagocytosis involves a large cell membrane-derived vesicle forming around macromolecules. Pinocytosis involves smaller vesicles forming around water and its dissolved solutes.
2. In receptor-mediated endocytosis, a molecule binds to a cell membrane protein receptor and causes the membrane to form a vesicle around the molecule and receptor. The vesicle with its contents enters the cell and usually fuses with a lysosome. An example is the endocytosis of lipoprotein particles from blood into liver cells.
3. Diatom wall components move from the Golgi apparatus to the cell wall by exocytosis.

WORK WITH THE DATA, P. 122

1. The mRNA-injected oocytes swelled because of osmotic uptake of water. At 4 minutes, the mRNA-injected cells had taken up so much water that they burst. The control cells did not take up excess water and therefore stayed intact.
2. Water permeability increased with more mRNA-injected, presumably because there was more aquaporin in the membranes that had more mRNA. The relationship could be evaluated statistically by linear regression.

3. The data on the mRNA-injected oocytes for mercuric chloride alone showed reduced water permeability, indicating that a protein was involved. Adding mercaptoethanol restored water permeability. There was not much water permeability in the controls without added mRNA, and mercuric chloride and mercaptoethanol had no effect on this.

FIGURE QUESTIONS

Figure 6.1 Hydrophobic interactions keep some proteins embedded whereas ionic attractions keep others on the surface.

Figure 6.10 Overfertilizing makes the soil water hypertonic to the interior of the plant root cells. Water leaves the plant roots by osmosis, moving toward the hypertonic medium. Water in the plant organs also travels to the roots, where it leaves by osmosis. Because cellular water is important in maintaining turgor pressure, the loss of water resulting from overfertilization causes the plant to wilt.

Figure 6.15 Blocking the Na^+/K^+ pump will result in equal concentrations of Na^+ inside and outside the cell. Generally, this will increase the cellular Na^+ . The absence of a Na^+ gradient will mean there is no potential energy to drive glucose uptake into the cell, so the glucose concentration will be reduced.

APPLY WHAT YOU'VE LEARNED

1. When measured at a constant temperature, the cell membranes show a trend toward greater fluidity with decreasing temperature of a species' native environment. The least fluid membranes are found in animals that experience the highest temperatures (rats with body temperatures of 37°C). Fluidity is slightly greater in desert pupfish at 34°C and increases even more in goldfish raised at 25°C . This trend continues with increasing fluidity in goldfish raised at 5°C . The greatest fluidity is observed in arctic sculpin raised in extremely cold temperatures (0°C).
2. The data suggest that the ratio of saturated to unsaturated fatty acids in phospholipids making up the membrane also influences its fluidity.
3. Saturated fatty acids can pack together more tightly than unsaturated fatty acids, reducing membrane fluidity. Shifting to a greater proportion of unsaturated fatty acids would be appropriate as temperatures decrease, because molecular motion decreases as temperature decreases. At very low temperatures, the membrane needs more unsaturated fatty acids to reduce tight packing and maintain fluidity. At very high temperatures, the membrane can accommodate tight-packing saturated fatty acids because molecular motion is greater.
4. From the fluorescence value, the graph indicates that the cell membranes of the animal must have been raised at a temperature of about 15°C . This temperature falls between data collected for goldfish at 5°C and 25°C . This means that the ratio of saturated to unsaturated fatty acids in this animal might be expected to fall somewhere between 0.66 and 0.82 based on the data provided in the table, and probably close to 0.70.

Chapter 7

RECAP 7.1

1. Autocrine signaling would be important for a cell to maintain a specialized role. For example, a cell might receive a signal to specialize and form a tissue of many cells. The first cell would self-stimulate to grow and divide to form the tissue in response to self-signaling.
2. Hormones are delivered to target-cell receptors through the circulatory system. In animals, this is blood; in plants, it is the vascular system.
3. Specificity for signal response occurs because only certain cells make the receptor for a given signal.

RECAP 7.2

1. The dissociation constant is the ratio of the rate constant for dissociation of a ligand and its receptor to the rate constant for binding. The higher the K_D , the less likely it is that a signal will bind to its receptor, and the less likely it is that a cell will respond to a signal at particular concentrations of ligand and receptor.
2. The chemical nature of receptor–ligand bonding is shape and the presence of noncovalent interactions, such as hydrophobic and ionic interactions. This provides specificity. Specificity is important to ensure an appropriate biological response to each signal.
3. Cytoplasmic receptors lack nonpolar regions that allow insertion into the cell membrane. Their exteriors are polar, so they can interact with water in the cytoplasm. While membrane receptors stay in the membrane, cytoplasmic receptors may be translocated to the nucleus after binding to their ligand.

RECAP 7.3

1. Amplification occurs because each activated ras molecule catalyzes the phosphorylation, and therefore activation, of many molecules of Raf, each of which in turn activates many molecules of MEK, etc. The general principle is one enzyme → many molecules of its substrate.
2. Different cells can have different target molecules to which cAMP binds, and these targets can have different activities and functions. Binding of cAMP changes the structure of its target (e.g., tertiary structure of a protein).
3. Regulation of cascades occurs in three ways: by differing concentration of a second messenger (e.g., NO is a gas that breaks down readily), by differences in concentration of a single component of the pathway, and by enzymes that change target molecules (e.g., phosphatases that remove phosphate groups on proteins in a cascade).

RECAP 7.4

1. Oxytocin is involved with both G protein–coupled and ion channel responses. It binds to a G protein–coupled receptor (see [Figure 7.7](#)), resulting in signal transduction through the IL_3 –DAG pathway, which releases Ca^{2+} into the cytoplasm via ion channels. In the brain, the effect of Ca^{2+} is to indirectly stimulate nerve cell activity by the opening of ion channels for Na^+ .
2. Ion channel opening is a rapid response to signaling. Enzyme modification is also a relatively rapid response mechanism. Changes in gene expression involve many steps, so cell signaling via transcription factors is slower.

RECAP 7.5

1. *Characteristics of direct communication by cell junctions:* The size of signal molecules is limited by the size of openings between cells. It is not specific. It is fast. There can be cytoplasmic connection between cells.
Characteristics of receptor-mediated communication: The signal molecules can be larger. It is specific. It is slower. There is no direct cytoplasmic connection. The advantage of direct communication over chemical signaling is that direct communication enables a rapid, coordinated response of many cells.
2. From single-celled *Chlamydomonas* evolved larger and larger groups of cells with communicating junctions (*Gonium*, *Pandorina*, *Eudorina*). Even larger groups had some differentiation (*Pleodorina* and *Volvox*).
3. Experiments might involve applying a solution containing the antibody to the upper part of the *Hydra* body. The antibody would block diffusion of the signal molecule from the apex to the upper body and—if the hypothesis is correct—would allow a bud to form in the upper body. A sham experiment, in which the solution without antibody is applied, would be a control. In this case, a bud would not form in the upper body.

WORK WITH THE DATA, [P. 143](#)

1. There was a higher level of trust in the donors who received oxytocin than in those who did not. The difference was about 15 percent. A *t*-test could be used to assess the difference for statistical

significance.

2. There was no difference in investment between oxytocin-treated and untreated people when they were told exactly how much to invest. This indicates that oxytocin does not just induce people to take a greater risk, but when considered with the results of the first experiment, oxytocin increases risk when there is a social interaction between people involving trust.

FIGURE QUESTIONS

Figure 7.3 As with the binding of enzyme to substrate, the binding of caffeine and adenosine is noncovalent. Both substances bind to a specific site on the receptor by their shape and by interactions, including hydrophobic interactions (the rings).

Figure 7.10 Raf activity is an early event in the protein kinase cascade that stimulates cell division in kidney cancer. Blockage of raf prevents phosphorylation of MEK, and all the subsequent steps in the protein kinase cascade. Cell division is reduced and the tumor shrinks.

Figure 7.17 Direct communication between cells allows them to rapidly share signals, which travel from one cell to another in a group. This can result in common activities for a group of cells, which is important for tissues.

APPLY WHAT YOU'VE LEARNED

1. The figure shows that different amounts of the membrane protein OmpC are produced and inserted into the membrane, depending on environmental solute concentration.
2. The membrane protein EnvZ is a protein kinase that phosphorylates itself and then phosphorylates OmpR in the cytoplasm. This sequential phosphorylation could explain how signal transduction occurs in this signal pathway.

3. The numbers of molecules of EnvZ are much smaller than the numbers of molecules of OmpR in the cytoplasm, suggesting that a smaller number of the membrane proteins act to stimulate a larger number of cytoplasmic proteins that carry the signal to the next point in the signal transduction pathway.

Chapter 8

RECAP 8.1

1. Exergonic reactions release free energy because the energy of the reactants is greater than that of the products. The reverse is true for endergonic reactions, which require an input of energy. ΔG is the free energy change of a reaction—products minus reactants. A positive ΔG means that the reaction is endergonic and requires energy, while a negative ΔG indicates that a reaction is exergonic and releases energy.
2. Endergonic reactions require the input of energy to create more ordered molecules. The second law of thermodynamics states that order tends to increase in the universe. Endergonic reactions are coupled in time and space with exergonic reactions, which increase the disorder and release the energy needed for the endergonic reactions to proceed. Overall, organisms need to take in energy from their environment continually to maintain these reactions.

RECAP 8.2

1. ATP has terminal phosphate groups that repel one another, so it takes energy to form a bond between them. Some of this energy is stored as potential energy. Also, hydrolysis of phosphate releases energy because the free energy of the P~O bond is higher than the free energy of the OH bond formed by hydrolysis.
- 2a. The reaction is endergonic (positive ΔG).
- b. ATP hydrolysis can drive the reaction ($\Delta G = -7.3$ kcal/mol).

RECAP 8.3

1. Enzymes have a three-dimensional (tertiary) structure with an active site in which the substrate fits. Chemical groups at the active site also bind to the substrate non-covalently.
2. While an enzyme-catalyzed reaction proceeds more rapidly to its equilibrium than an uncatalyzed reaction, the actual equilibrium point is unaffected.
- 3a. The presence of water may prevent O_2 from reaching the enzyme.
- b. Boiling denatures proteins, so polyphenol oxidase is irreversibly altered by boiling, and its active site is destroyed.

RECAP 8.4

1. As part of the catalysis, an enzyme can add or remove H^+ in a substrate, which may facilitate reaction with the substrate. The course of these H^+ reactions involves acidic or basic R groups on amino acids at the active site. Metal ions of enzymes may gain or lose electrons during the reaction, donating them temporarily to the substrate.
2. Coenzymes are small and nonprotein; enzymes are large proteins or RNA. Coenzymes do not catalyze reactions; enzymes are catalysts. Coenzymes add or remove chemical groups (e.g., H^+) and are permanently changed as a result of the reaction; enzymes are not permanently changed by participating in a reaction.
3. At the beginning, the reaction rate will increase linearly with added enzyme since the enzyme will be saturated with substrate even after many additions. Thus the reaction rate will increase proportionally with the amount of enzyme added, but only until the enzyme is no longer saturated with substrate. At this point the enzyme will be present in excess with respect to substrate, and additional enzyme will have no additional effect. The curve will level off to a constant maximum rate when this point is reached.

RECAP 8.5

1. Feedback inhibition occurs in a biochemical pathway when that pathway's end product can act as an inhibitor of the enzyme that catalyzes the first step in the pathway. In a systems diagram, each node represents an enzymatic transformation. Feedback inhibition can cross multiple pathways, thereby allowing the changing concentration of one molecule to affect several pathways that lead to its synthesis.
2. See [Figure 8.17](#). A competitive inhibitor binds to the active site of the enzyme and shifts the equilibrium to enzyme molecules in the active form.
3. To determine whether catalase has an allosteric or a nonallosteric mechanism, perform an experiment with varying amounts of substrate and plot the rate of cat-alase-versus-substrate concentration. An S-shaped curve will indicate an allosteric mechanism. A hyperbolic curve will indicate a nonallosteric enzyme. To determine if a pollutant is a competitive or a noncompetitive inhibitor, add the pollutant to the catalase to lower the rate of reaction, then add increasing amounts of substrate. A competitive inhibitor will be removed from the active site and the rate of reaction will increase. A noncompetitive inhibitor will not allow the rate to increase as more substrate is added.

WORK WITH THE DATA, [P. 165](#)

1.

2. There is an inverse relationship between enzyme activity (PG synthesis) and aspirin concentration, so aspirin is an inhibitor of the reaction in lung tissue homogenates. Because aspirin also inhibited PG synthesis in human platelets, we can conclude that inhibition occurs in different tissues of different organisms.
3. In all three individuals, aspirin given in vivo inhibited PG synthesis by platelets. This generalizes the results from the test tube experiment to a living organism.

FIGURE QUESTIONS

Figure 8.7 The synthesis of ATP has a ΔG of +7.3 kcal/mol. So any reaction driving this synthesis must have a ΔG of at least -7.3 kcal/mol. Because of the second law of thermodynamics, the transfer of energy is not efficient (entropy increases), so the ΔG of the driving reaction would be more than +7.3 kcal/mol.

Figure 8.8 Yes. In this case, activation energy is needed to make the substrate(s) able to take up energy and then the reaction proceeds.

Figure 8.12 No. Typically, the tertiary structure of a protein is due to weak non-covalent forces such as hydrophobic interactions, ionic attractions, and hydrogen bonds. Binding of substrate alters these forces but not covalent bonds.

Figure 8.19 Lysosomal enzymes have an amino acid sequence and therefore tertiary structure that

exposes their active site at pH 4.8. At pH 7.2, the tertiary structure does not expose the active site, so the enzyme is inactive.

APPLY WHAT YOU'VE LEARNED

1. The molecules are luciferin, oxygen, ATP, and magnesium ion. Luciferin reacts with oxygen to undergo chemical change that involves emission of light as this change takes place. In order to drive this reaction, phosphate bonds in ATP are hydrolyzed, which releases chemical energy. Some of this energy is then released in the form of light as luciferin and oxygen react. Magnesium ion is needed as a cofactor of the enzyme that catalyzes reactions involving the other molecules.
2. The firefly takes in food as a source of chemical energy. As the food is digested, some of the chemical energy in the bonds of the food molecules is stored in phosphate bonds of ATP as ADP is phosphorylated to form ATP. This chemical energy is then released when ATP is hydrolyzed during the luciferin reaction, with some of the energy released in the form of light.
- 3.

4. The enzyme's catalytic activity is abolished when the enzyme is heated. The catalytic activity is also affected by changes in pH. The effect of heating is likely due to disruption of the enzyme's tertiary structure by high heat; most proteins cannot maintain their active shape if they are exposed to high heat. The effect of changing pH is likely due to changes in ionization of basic amino acid side chains of lysine and arginine or acidic side chains of aspartic acid and glutamic acid. Changes in ionization in these side chains can affect binding of the substrate or interactions between groups within the enzyme that stabilize its three-dimensional structure.
5. This is an example of induced fit, which the enzyme uses to orient substrates with one another and with amino acid side chains of the enzyme that are important in its catalytic mechanism. This shape change of the enzyme excludes water from the active site, ensuring that ATP will not be hydrolyzed by water and will react only with luciferin to transfer AMP and release pyrophosphate, PP_i.

Chapter 9

RECAP 9.1

1. A complex chemical transformation occurs in a series of separate reactions that form a metabolic pathway. Each reaction is catalyzed by a specific enzyme. Many metabolic pathways are similar in all organisms, from bacteria to humans. In eukaryotes, many metabolic pathways are compartmentalized, with certain reactions occurring inside specific organelles. Some key enzymes in each metabolic pathway can be inhibited or activated to alter the rate of the pathway.
2. NAD⁺ is a reducing agent (it accepts electrons), and O₂ is an oxidizing agent (it donates electrons).
- 3a. It is an oxidation (removal of H from C2 and C3 of succinate).
 - b. It is exergonic, because it is an oxidation.
 - c. It requires the redox coenzyme NAD or FAD.

RECAP 9.2

1. In glycolysis, the net yield is 2 ATP per glucose and 1 NADH per glucose.
2. Pyruvate oxidation produces the two-carbon molecule acetyl CoA, which is activated and then participates as a first substrate in the citric acid cycle.

3. The citric acid cycle regenerates the four-carbon acceptor molecule for the next acetyl CoA from pyruvate. Glycolysis does not regenerate a starting material.

RECAP 9.3

1. A series of electron carriers in the inner mitochondrial membrane transports electrons by reduction–oxidation. As the electrons are added to each carrier, protons are transported via the carrier into the intermembrane space.
2. The experiment in [Figure 9.9](#) shows that in the absence of electron transport, a gradient of protons across the membrane is sufficient to produce ATP if the ATP synthase is present in the membrane. The experiment in [Figure 9.10](#) shows directly that ATP synthase can carry protons from a gradient, harnessing the potential energy from the gradient to make ATP.
3. If cytochrome *c* remains reduced and cannot accept electrons, the electron transport (respiratory) chain stays reduced and NADH and FADH₂ remain reduced. This prevents oxidation reactions in the citric acid cycle and pyruvate oxidations, so pyruvate cannot be converted to acetyl CoA. Instead, pyruvate is converted to lactic acid, regenerating some NAD that can be used so that glycolysis can continue. Because the electron transport chain is not working, no proton gradient is set up in the mitochondria, and ATP is not made by oxidative phosphorylation.
4. If antimycin A were present, it would make no difference to the results of the experiment, since an artificial proton gradient was already set up.

RECAP 9.4

1. NAD⁺ is an electron acceptor for reactions in glycolysis and pyruvate oxidation. If it is not present in its oxidized form, the oxidation of these substrates in the two reactions does not occur, and the pathways stop.
2. Fermentation replenishes NAD⁺ by oxidizing NADH during chemical oxidations forming lactate or ethanol from pyruvate.

RECAP 9.5

1. *A catabolic interconversion of a lipid:* Fatty acids are catabolized to acetyl CoA. This enters the citric acid cycle and is oxidized to CO₂, providing reduction energy to form NADH and FAHD. *An anabolic interconversion of a protein:* Amino acids are converted to intermediates in glycolysis and the citric acid cycle. These intermediates can be used in anabolism to form glucose, fats, or other amino acids to make proteins.
2. Phosphofructokinase acts early in glycolysis and is a focal point for turning off or activating the rest of the energy pathways. It is turned off by later products (ATP, citrate) and turned on when energy is needed (ADP).
3. Some amino acids are converted to intermediates of glycolysis. Once they enter glycolysis, these intermediates are further metabolized to a glycolytic intermediate that can be converted to glycerol, which is incorporated into triglycerides. Glycolysis and pyruvate oxidation produce acetyl CoA, which is converted to fatty acids and incorporated into lipids. Glucose is converted in glycolysis to acetyl CoA, which is then converted to fatty acids as above.

WORK WITH THE DATA, [P. 183](#)

1. Both groups of mice gained weight as they aged, but the mutant mice gained less weight than the normal mice.
2. The amount of food eaten and the levels of exercise were the same for both groups. So the lower weight gain in the mutant mice was not due to food intake or exercise.
3. UCP1 levels were much higher in the mutant mice than in the normal mice. The correlation between higher UCP1 and lower weight gain indicates that uncoupling of mitochondrial ATP synthesis from electron transport in brown fat may be responsible for lowered weight gain.

FIGURE QUESTIONS

[Figure 9.3](#) The H atom comes from the oxidation of a substrate.

[Figure 9.7](#) –20 kcal/mol

[Figure 9.13](#) DNA can be an energy source. When DNA is hydrolyzed, the nucleotides can be metabolized into intermediates in the citric acid cycle. The intermediates are then oxidized and the energy released to reduced coenzymes, which release their energy when oxidized in the mitochondria to form ATP. However, because it is the genetic material and must be preserved, DNA is protected from hydrolysis after it is made by being sequestered in the cell nucleus.

APPLY WHAT YOU'VE LEARNED

1. The body first uses glucose supplied from the last meal, then begins to break down glycogen. Once all of the glycogen is gone, the body makes glucose through gluconeogenesis using molecules present in the

body.

2. Mammals break down proteins and use amino acids to make glucose through gluconeogenesis. Mammals also use glycerol from triglycerides, but they do not use fatty acids in this way. Fatty acids do not stimulate gluconeogenesis.
3. The person will lose muscle mass because proteins in muscle cells will be broken down to make glucose via gluconeogenesis. This is not advisable because this will weaken the person's body and put him or her in a state of low body fitness. People generally do not realize this because they think that dieting will cause loss of fat rather than muscle.
- 4.

Any of the carbon atoms in alanine could be labeled with carbon-14 to trace it through the gluconeogenesis pathway, since only the NH₃ group is removed from the alanine carbon chain.

Chapter 10

RECAP 10.1

1. The light reactions convert light energy into chemical energy in the form of ATP and NADPH. In the light-independent reactions, ATP and NADPH power the fixation of CO₂ to form carbohydrate. NADP and ADP are regenerated.
2. Researchers used the isotope ¹⁸O to show that the O₂ produced during photosynthesis came from water labeled with ¹⁸O and not from carbon dioxide labeled with ¹⁸O.

RECAP 10.2

1. A pigment molecule tends to lose the absorbed energy of a photon by returning to ground state and emitting the energy as light or heat. Alternatively, the energy can be transferred as an excited electron from the pigment to another molecule, reducing that molecule.
2. An absorption spectrum plots the extent of absorption by pigments (y axis) versus the wavelength of light to which the pigments are exposed (x axis). An action spectrum also plots wavelengths of light, but in this case the y axis is a biological activity (e.g., photosynthesis).
3. See [Figure 10.8](#). In cyclic electron transport, ATP is produced chemiosmotically by electron transport in the thylakoid membrane.

RECAP 10.3

1. Researchers exposed algae to CO₂ labeled with ¹⁴C for varying times and looked to see where the ¹⁴C label ended up. After a very short exposure time of 3 seconds, all of the label was found in 3-phosphoglycerate (3PG). After a longer exposure time of 30 seconds, the label could be found in more compounds, suggesting that 3PG is the initial product that is then used for synthesis of additional molecules. See [Figure 10.10](#).
 - a. The light reactions produce ATP and NADPH, which are used in CO₂ fixation reactions (Calvin cycle).
 - b. Light-induced pH changes in the stroma activate some Calvin cycle enzymes.
 - c. Light-induced electron transport reduces disulfide bridges in four of the Calvin cycle enzymes, thereby activating them.
2. In the dark, photosynthetic electron transport stops at photosystem II → reduced PQ (plastoquinone). Initially the chlorophylls in light-harvesting complexes remain reduced, so reaction center chlorophylls remain reduced and thus photosystem II remains reduced. In the dark, the Calvin cycle stops at the reduction phase, which requires NADH. No RuBP is regenerated, so there is no rubisco activity. The initial reactions are no oxidation of photosystem I and no reduction of NADP to NADPH.

RECAP 10.4

1. In C₄ plants, CO₂ is initially fixed in the leaf mesophyll cells but is then transferred (as a four-carbon molecule) to the bundle sheath cells, where decarboxylation reactions release CO₂ for use in the Calvin cycle. The bundle sheath cells are located in the interior of the leaf where less atmospheric O₂ can reach them than reaches cells near the surface of the leaf.

2. In CAM plants, CO₂ is initially fixed into a four-carbon compound (malate) at night when it is cooler and water loss is minimized, and the stomata open. During the day, when the stomata close to reduce water loss, the accumulated malate is transferred from the vacuole to the chloroplasts, where its decarboxylation supplies the CO₂ for the Calvin cycle and the light reactions supply the necessary ATP and NADPH.

RECAP 10.5

1. See [Figure 10.17](#). 3PG and G3P link the Calvin cycle and glycolysis. Acetyl CoA links glycolysis to the citric acid cycle.
2. Most of sunlight is not absorbed by plants. This is because it has wavelengths that are not part of the absorption spectrum of plant pigments; because it is reflected back to space; and because it is not intercepted by plant organs (e.g., it reaches the ground).

WORK WITH THE DATA, P. 195

1. In Experiment 1, the ¹⁸O/¹⁶O ratio of O₂ (0.84–0.86) was similar to that of the H₂O (0.85) and not to that of the CO₂ sources (0.2–0.61). In Experiment 2, the ratio in O₂ (0.20) was again more similar to that of the H₂O (0.20) than to that of the CO₂ sources (0.40–0.50).
2. The source of the oxygen atoms in O₂ is H₂O.

WORK WITH THE DATA, P. 203

1.

The data show an initial rise of 3PG (in first 30 sec) because rubisco is initially still active and can catalyze the reaction of CO₂ with RuBP to produce 3PG. Between 30 sec and 2 min, the amount of 3PG levels off as rubisco becomes inactive in the dark. After 2 min, the amount of 3PG falls as it enters other pathways (see [Figure 10.18](#)).

2. The level of RuBP went down in the dark initially because it was consumed in the reaction catalyzed by rubisco.

FIGURE QUESTIONS

[Figure 10.2](#) Reduction occurs in the stroma of the chloroplast and the reducing agent is NADPH.

[Figure 10.4](#) In phycobilins, yellow light absorbs at a shorter wavelength (540 nm) that is more energetic than the longer wavelength (660 nm) at which chlorophyll absorbs. This means that the energy transfer from phycobilins to chlorophyll is thermodynamically favored (higher to lower energy).

[Figure 10.7](#) The herbicide rather than NADP reductase would accept electrons from noncyclic photosystem I. NADPH would not be formed. This would severely reduce the transfer of solar energy to chemical energy in the light-requiring reaction system.

APPLY WHAT YOU'VE LEARNED

1. Light stimulates the light reactions to occur, which then stimulates the Calvin cycle. Also, light-induced changes activate Calvin cycle enzymes.
2. Shade-tolerant plants have much lower maximum rates of photosynthesis even when raised in the same light conditions as shade-intolerant plants and exposed to the same light intensities. This suggests that

either there are fewer light-harvesting centers and fewer Calvin cycle enzymes in shade-tolerant plants, and/or that the Calvin cycle enzymes of shade-tolerant plants are adapted to function at lower rates than those of shade-intolerant plants.

3. Both shade-tolerant and shade-intolerant plants develop more chlorophyll when raised under greater degrees of shade. This helps compensate for the low light levels to allow the plants to collect greater amounts of light.
4. Specific leaf surface areas are larger in shade-tolerant plants. This allows the light-harvesting centers to be spread out as much as possible so that they can capture maximum light under shade conditions. This helps compensate for the low light levels to allow the plants to collect enough light to carry out photosynthesis.
5. The shade-intolerant plants will have a much greater fluctuation in photosynthesis rate than the shade-tolerant plants. This prediction is made based on the much larger range of photosynthesis rate data in the graph of the shade-intolerant species compared with that of the shade-tolerant species.

Chapter 11

RECAP 11.1

1. A common signal for the initiation of binary fission is adequate nutrients.
2. If the cell divided before DNA was fully replicated, each new cell would not receive a full complement of the genetic material, DNA.
3. In eukaryotes there is more DNA, the DNA is in numerous molecules, the DNA molecules are much larger, and the DNA is located in a separate cell compartment, the nucleus.

RECAP 11.2

1. See [Figure 11.3](#).
2. The Cdk's are made throughout the cell cycle. However, their protein kinase active site is not available for target substrates for cell cycle activities unless a particular cyclin molecule binds to the Cdk. It is the cyclins that are made, bind to Cdk's to activate, and then break down. The transient nature of the cyclins controls each Cdk activation in sequence at the cell cycle control points.
3. Growth factors are proteins made by cells that can travel to other cells, or act on the cells that make them, usually to stimulate cell division. Growth factors bind to specific receptors on target cells, setting off signal transduction inside the cells. This can lead to gene expression for cyclins, for example, and the cell cycle is stimulated.
4. P16 blocks the interaction of cyclin and its Cdk that act at the G1–S boundary. If there is more p16 in older people, it may mean that their cell cycle is blocked and they cannot repair damaged tissues by cell replacement.

RECAP 11.3

1. A chromosome is a DNA molecule in the cell, and when the cell is in mitosis the chromosome is complexed with proteins to produce a visible, condensed structure. A chromatid is a DNA molecule complexed with proteins that is the product of S phase DNA replication. Chromatids are in pairs (the two products of replication) and lie attached to one another via the centromere until anaphase of mitosis. A daughter chromosome appears in an anaphase of mitosis, and was formerly a chromatid but has now separated from its partner as it migrated to the spindle pole.
2. During interphase, DNA is somewhat condensed by histone proteins into nucleosomes, and these fold over one another to form chromatin fibers. During prophase, the fibers attach as loops to proteins, and these in turn loop extensively to form the chromosome.
3. Chromosomes are attached to spindle microtubules, and molecular motors on the microtubules move the chromosomes along. In addition, spindle microtubules shorten from the poles, and this causes the attached chromosomes to move to the poles. Taxol prevents these processes, and so inhibits cell division. The drug also inhibits the division of normal cells that enter M phase.
4. In plant cells, a cell plate forms from Golgi vesicles and this makes a new cell wall to separate the two daughter cells. Cell membranes grow below the cell walls. In animal cells, a "purse string" of microfilaments contracts to pinch off the cell membrane, and the cells separate.
5. A nonfunctional cohesion would not allow close attachment of chromatids during cell division, and there would not be a centromere. The two chromatids would be separate and there would be no organization for kinetochore attachment. There would be ineffective segregation of one chromatid of a pair to each daughter cell.

RECAP 11.4

1. Take a dividing cell and examine the chromosomes. If each chromosome differs in size and centromere placement from the others, the plant sample is haploid. If there are two copies of each chromosome, the

plant is diploid.

2. Fertilization involves the union of two haploid gametes, each with one set of chromosomes, made from meiosis. So the fertilized cell is diploid.
3. All sexual life cycles have some haploid and diploid cells, fertilization, and meiosis.
4. See [Figure 11.14](#).

RECAP 11.5

1. In crossing over, there is an exchange of some genetic material between non-identical chromosomes of a pair. So the resulting chromosomes carry new combinations of genes, which can be passed on to offspring in a gamete and fertilization. In independent assortment, it is random which chromosome of a homologous pair ends up in a particular gamete. So different gametes will usually have a different set of chromosomes; that is, chromosome 1 from the father, chromosome 2 from the mother, and so on. Fertilization therefore results in diploids, each of which has a different set of chromosomes.
2. *Prophase I meiosis*: Chromosomes have chromatid pairs attached, and the two homologs are lined up gene for gene beside one another.
Prophase mitosis: Chromosomes have attached chromatid pairs but are not lined up beside one another.
Anaphase I meiosis: Homologous chromosomes, each with two attached chromatids, separate and move to the poles.
Anaphase of mitosis: Chromatids separate and become single daughter chromosomes and move to the poles.
3. In the formation of male gametes, the X and Y chromosomes fail to separate in meiosis I anaphase. At the end of meiosis II, there will be two types of gametes: half without an X or Y, and half with X and Y. If the latter fertilizes a normal egg with a single X chromosome, the offspring will be XXY. However, if there is a similar nondisjunction in the formation of female gametes, there will be eggs with two X chromosomes. If the XX egg is fertilized by a normal, Y-containing sperm, the offspring will be XXY.
4. Polyploidy refers to an extra set or more of chromosomes (e.g., $3n$ instead of $2n$). It arises because of failure of all chromosomes to disjoin in meiosis in gamete formation, resulting, for example, in a diploid gamete.

RECAP 11.6

1. Signals for necrosis include great damage to a cell or starvation.
2. Apoptosis is necessary when cells are damaged and could be mutated, and when there are too many cells for organ structure.
3. Apoptosis is regulated by signals such as hormones and DNA damage, and a signal transduction pathway that results in apoptotic processes.

RECAP 11.7

1. Normal cells: have control over cell division; stay in tissue and do not migrate. Malignant tumor cells: lose control over cell division; migrate to other places in the body. Benign tumor cells: lose control over cell division and then at some point stop dividing; do not migrate to other parts of the body.
2. In normal cells, oncogene products are not active or are made in low amounts, while in cancer cells oncogene products are made in larger amounts or mutated forms, and these act to stimulate the cell cycle. In normal cells, tumor suppressor gene products are made and are active at blocking the cell cycle. In cancer cells, tumor suppressor gene products are either mutated to be nonfunctional or are not made, and in either case are not active in blocking cell division, so cells divide and form tumors.
3. Cancer cells are not synchronous in the cell cycle. At a given point in time, some are in G1, some in S, and so on. So targeting all the phases might be better than targeting just one.

WORK WITH THE DATA, [P. 217](#)

1. Labeling of the G1 nuclei in the G1/S cells was mostly complete by 16 hours.
2. The G1 control showed when DNA replication would normally occur in G1 nuclei. The G1/G1 control showed that the fusion process itself did not stimulate DNA replication; G1 cells had to be fused to S cells for DNA replication to be stimulated. Nuclei of the G1 and G1/G1 cells did not start to become labeled until about 8 hours after fusion, because these cells had to go all the way through G1 before entering S and replicating their DNA. By contrast, labeling of the G1 nuclei in the G1/S cells began soon after fusion.
3. G2 cells are further into the cell cycle than S phase cells are. It took several hours for the S phase cells to pass through S and G2 to begin mitosis.
4. The timing of mitosis in the hybrid S/G2 cells was similar to that in the unfused S cells and the S/S hybrids. This result indicates that G2 cells cannot stimulate mitosis of nuclei that are still in S phase.

FIGURE QUESTIONS

[Figure 11.3](#) 6 pg

[Figure 11.21](#) Apoptosis may be a way to eliminate cells that might develop mutations causing the cell to

be harmful to the organism, such as a normal cell turning into a cancer cell. In addition, as an organism develops, organs must be a defined size and shape. Apoptosis may eliminate excess cells that would make an organ too big or misshapen.

Figure 11.25 The cell cycle treatments affect the cell cycles of all dividing cells in the body, not just those of the tumor cells. By contrast, targeted drugs affect altered proteins present only in tumor cells. The side effects of the general cell cycle drugs would be on organs and systems that rely on dividing cells. For example, blood cells undergo apoptosis after a period in the bloodstream and must be replaced by dividing cells; if division in these cells is blocked by an anticancer drug, the patient may develop side effects such as poor immunity (too few white blood cells) and anemia (too few red blood cells).

APPLY WHAT YOU'VE LEARNED

1. Cells would halt at various points in the cell cycle:
Extract 1: cells would accumulate in G2.
Extract 2: cell would accumulate in M.
Extract 3: cells would accumulate in G1.
Extract 4: cells would accumulate in S.
2. Different cells in a tumor may have different errors in cell cycle control. One cell may respond to a G1 inhibitor and another cell to an S phase inhibitor.
3. The researcher could isolate compounds from each cell extract and test them individually in the same tests carried out with the extract in order to locate the specific molecule that acts as an inhibitor in each case. These molecules can be analyzed to determine their chemical structures in order to synthesize them and carry out additional tests, including animal tests, to ensure that they are safe.
4. Only one protein is overexpressed in cancer cells compared with non-cancer cells, and that protein is Cdk1, which functions at the checkpoint during mitosis. The plant extract that inhibits the cyclin B–Cdk1 complex was extract #2, and so extract #2 would be the best choice for treating this tumor.
5. Researchers would be interested in the plant extract that halted phosphatase activity but not the extract that halted kinase activity. Phosphatase activates Cdk, which leads to progression through the checkpoint. The goal of an anticancer drug is to stop progression through the checkpoint so cell division stops. Therefore it would be desirable to inhibit the phosphatase that activates Cdk. It would not be desirable to inhibit the kinase, which is already doing what is necessary to inhibit Cdk.

Chapter 12

RECAP 12.1

1. The F1 generation showed only one phenotype and it was a parental phenotype; blending predicted that the F1 would show an intermediate phenotype, not like either parent. The F2 generation also showed the phenotype of the other parent, not seen in the F1; blending predicted that the phenotype would disappear.

2.

3. $BB \times bb$; $bb \times bb$; $Bb \times bb$; $Bb \times Bb$.

4a. Autosomal dominant.

b. $\frac{1}{4}$

RECAP 12.2

1. In codominance, in a heterozygote both alleles are evident in the phenotype. In incomplete dominance, in a heterozygote an intermediate phenotype between the parents is seen.

2. In blood type AB, 1. Cells would halt at various points in the cell cycle:

3. Yellow, blue, and white in a 1:2:1 ratio.

RECAP 12.3

1. Penetrance is the proportion of individuals with a certain genotype that actually show the phenotype associated with that genotype; that is, what both the A and B alleles are expressed. On the red blood cell surface, two types of proteins are seen. the extent to which a genotype actually shows its associated phenotype; that is, are all the pea plants with proportion of pea plants with "Tall" genotype are tall? Expressivity is

2. Qualitative variation involves phenotypes, such as colors and textures, that cannot be easily measured; for example, green and yellow peas. Quantitative variations are phenotypes that can be measured; for example, tall and short pea plants.

3. 75%

RECAP 12.4

1. In genetic linkage, alleles on the same chromosome are generally carried together when a gamete is formed. That is, if in a heterozygote $AaBb$ the A and B are on the same chromosome (and a and b on the other chromosome), gametes will be AB or ab .

2.

3.

4. A sex-linked gene is carried on the X chromosome. In a genetic cross involving an organism with the XY system for sex differentiation, a sex-linked gene usually has no counterpart on the Y chromosome. So in an XY male, all X-linked alleles, dominant or recessive, are expressed in the phenotype.
5. The cross $RRYY \times rryy$ produces $RrYy$ (round, yellow) F_1 offspring. If the seed shape and seed color genes were linked with no recombination between them, the F_2 would also be all $RrYy$. A distance of 10 map units between two genes means that on average 10% of the F_2 offspring will have recombinant phenotypes, in this case round green (5%) and wrinkled yellow (5%). The cross in [Figure 12.19](#) is $BbVgvg$ (gray, normal) $\times$ $bbvgvg$ (black, vestigial). If there were no linkage between the genes, then the gray, normal parent would produce four types of gametes: BVg , bVg , Bvg , and bvg . When these combine with the bvg gametes produced by the other parent, four types of offspring in a 1:1:1:1 ratio will result: $BbVgvg$ (gray, normal), $bbVgvg$ (black, normal), $Bbvgvg$ (gray, vestigial), and $bbvgvg$ (black, vestigial).
- The body color (G/g) and wing size (A/a) genes are linked; eye color (R/r) is unlinked to the other two genes. The distance between the linked genes is 18.5 units.

Recap 12.5

1. Because the gene is carried on mitochondrial DNA, it is passed through the mother only. Thus if the women does not have the disease but her husband does, their child will not be affected. However, if the woman has the disease but her husband does not, their child will have the disease.

RECAP 12.6

1. Mating and recombination allows genes to be exchanged between bacteria and results in a genetically diverse population of these organisms. Because they are haploid, any new gene combinations will be expressed in the recombined offspring.
2. A plasmid that integrates into the host chromosome will be stable when the cell divides and therefore any genes on the plasmid will be expressed. In addition, if the bacterium mates, the genes on the plasmid may be transferred to another cell.
3. Plasmids can carry genes that confer antibiotic resistance. When a bacterium carry a plasmid mates with one that does not, the plasmid replicates and transfers one of the copies to the recipient bacterium. Now there are two bacteria with antibiotic resistance.

WORK WITH THE DATA, P. 243

1. The chi-square goodness-of-fit test is explained in [Appendix B](#), on [pp. 1285-1286](#). The formula for calculating chi-squared is given in Research Tools Figure B12.

Cross	Chi-squared	P-value
1	0.33	0.57
2	0.69	0.40
3	0.02	0.8
4	0.24	0.59
5	1.52	0.21
6	0.05	1
7	0.19	0.66
8	1.41	0.23
9	0.19	0.66
10	0.35	0.55

- All the individual crosses have P -values greater than 0.05, so no significant difference from a 3:1 ratio.
2. Combined data: Chi-squared 0.11, $P = 0.74$. In this case, similar P -values were obtained both for the individual crosses (small sample size) and for the combined dataset (large sample size).

WORK WITH THE DATA, P. 257

1. Using a chi-squared test with 3 degrees of freedom the chi-squared value is 429.96 and the P -value is less than 0.0001. This indicates a highly significant deviation from the expected 9:3:3:1 ratio.
2. The genes are linked, because there more parental type phenotypes and fewer recombinant (non-parental) phenotypes in the test cross progeny than would be expected for unlinked genes. The map distance is:

$$[(578 + 307) / (578 + 307 + 1413 + 1117)] \times 100 = 26 \text{ map units}$$

These data are different from the data shown in [Figure 12.17](#), because the parental types are different: black normal and gray vestigial in this cross, and gray normal and black vestigial in [Figure 12.17](#).

3. *BBVgVg* and *bbvgvg*

FIGURE QUESTIONS

[Figure 12.2](#) 7

[Figure 12.11](#) Yellow: *BBee* and Brown: *bbEE*.

[Figure 12.18](#) Heterozygous, *XRXr*. The female parent passed the *Xr* chromosome to the offspring, which had a Y chromosome from the male parent.

APPLY WHAT YOU'VE LEARNED

1. F_1 genotype: 100% *DdBb*.
 F_1 phenotype: 100% long legs, gray body
 F_2 genotypes: 1:2:1 ratio 25% *DDbb*:50% *DdBb*:25% *ddBB*
 F_2 phenotypes: 25% long legs, black body; 50% long legs, gray body; 25% short legs, gray body
2. F_1 genotype: 100% *BbCc*.
 F_1 phenotype: 100% gray body, straight wings
 F_2 genotypes: 1:2:1 ratio 25% *BBcc*:50% *BbCc*:25% *bbCC*
 F_2 phenotypes: 25% gray body, curved wings; 50% gray body, straight wings; 25% black body, straight wings
3. In the F_2 generation of the *DDbb* $\times$ *ddBB* cross, you would also find the short legs, black body phenotype (*ddbb* genotype), which would be a new phenotype not observed earlier.
 In the second case, the F_2 generation of the *BBcc* $\times$ *bbCC* cross, you would find the black body, curved wings phenotype (*bbcc* genotype), which would be a new phenotype not observed earlier.
 The *BBcc* $\times$ *bbCC* cross would produce the larger frequency of recombinants because the distance between the two linked loci (*B* and *C*) is longer ($75.5 - 48.5 = 27.0$ map units) than the distance between the two linked loci (*D* and *B*) ($48.5 - 31.0 = 17.5$ map units). There is a greater probability of crossing over with a longer distance between linked loci.

4.

Chapter 13

RECAP 13.1

1. DNA was located in the eukaryotic cell nucleus, where chromosomes carrying genes were located. The amount of DNA was the same in somatic cells of an organism, and halved in the products of meiosis, as expected by the genetic material. Different species had different amounts of DNA, just as they seemingly had different numbers of genes.
2. Avery and his colleagues performed genetic experiments using cell extracts of one strain of bacteria (A) that could change a recipient strain (B) that was genetically different into the extracted strain (A). When they pretreated the extract of the donor strain with enzymes that hydrolyzed proteins, transformation still occurred. So proteins in the donor extract were not responsible for genetic transformation.
3. Bacteriophage T2 has only two types of molecules, DNA and protein. So labeling one or the other could indicate which got into a host cell to cause genetic changes.
4. The proposed experiments might use S strain pneumococcus and transform R strain, as in [Figure 13.1](#). Incubate separate batches of S strain bacteria in ^{32}P or ^{35}S . Make cell-free extracts of the S strains. Incubate with R cells and look for their transformation to the S phenotype. Then check to see if there is ^{32}P or ^{35}S label in the newly transformed cells. It would be expected that only ^{32}P label (DNA) would enter the cells.

RECAP 13.2

1. X-ray diffraction indicated that DNA is double-stranded and twisted into a helix. There were indications that the bases were inside the helix, and the sugars and phosphates on the outside. Base composition data from many organisms showed that the percentages of the purine A = those of the pyrimidine T, and that the percentages of the purine G = those of the pyrimidine C. This suggested that A might be opposite T on the inside of the double helix, and G opposite C. When Watson and Crick built molecular models with the atoms and bonds of polynucleotide strands, the base pairing was confirmed, as the A-T and G-C pairs fit nicely together.
2. The double-stranded structure is essential in the replication of DNA, as the opposite strands can each act as a template for a new strand, so that two new identical strands are made. This is key in the replication of the genetic material when cells divide. The two strands can unravel at places, exposing the bases in the inside for gene expression. This is important because genes must be expressed for the phenotype.
3. The bases in DNA expose chemical groupings that can interact with groups on proteins. These include polar groups (e.g., $\text{C}=\text{O}$) on the bases that can attract oppositely polar groups (e.g., NH_2) on proteins, as well as form hydrogen bonds with groups on proteins.

RECAP 13.3

1. The bacteria were prelabeled with both strands of DNA with heavy ^{15}N . After one round of replication in

light 14N, three models for DNA replication had different predictions:

- Conservative: There would be original DNA (all heavy) and new DNA (all light) in equal amounts. This did not occur.
 - Dispersive: There would be light, heavy, and intermediate DNA in no fixed proportions. This did not occur.
 - Semiconservative: There would be only intermediate DNA, with one light and one heavy strand. This did occur.
- The five proteins involved in DNA replication are DNA helicase (unwinds the double helix), single-strand binding proteins (stabilize and keep apart the two strands in unwound regions), primase (binds to DNA to make a short primer), DNA polymerase (adds nucleotides to a growing chain), and DNA ligase (seals up nicks in DNA, due to its lagging strand replication in short pieces).
 - The special sequences at the ends of chromosomes are called telomeres, and they can be replicated if necessary. After DNA replication, the primer regions at the 3' ends of the long DNA in chromosomes are removed. This shortens the DNA and makes it unstable. In some cells, such as gamete-producing cells and cancer cells, the telomeric sequences are recognized by an enzyme complex called telomerase, which catalyzes the replication of any lost telomeric sequences and keeps the DNA at its original length.
 - DNA replication adds new nucleotides to the 3' end of DNA, where there is an —OH group on the sugar at the 3' position. If there is no —OH group, there cannot be a condensation reaction and formation of a bond to the next nucleotide, so replication stops.

RECAP 13.4

- If there were a mutation in S phase before meiosis (e.g., a T changed to a C), the replicated strand would be mispaired; e.g.,

```
AAGGTT ----- AAGGCT
>
TTCCAA          TTCCAA
```

If this mispairing was not recognized and repaired, a gamete formed might have the mutation:

```
AAGGCT
TTCCAA
```

And after the cell containing the mutation divided, one of the daughters would have the mutation and the other would retain the normal sequence.

```
Top strand      AAGGCT
replicated:     TTCCAA
                 Mutation
Bottom strand   TTCCAA
replicated:     TTCCAA
                 Normal
```

- If the colon cancer cell had a mutation in a tumor suppressor gene, it might not be repaired. This would lead to unregulated cell division.

RECAP 13.5

- Primers in PCR bind to a short region of DNA and allow elongation of that strand of DNA when DNA polymerase is added along with nucleotide.
- If a primer has a species-specific sequence—that is, a sequence of nucleotides complementary to a sequence unique to a certain organism—PCR will amplify a target DNA extracted from a field sample that has the unique sequence. This amplification will show that the organism with that sequence is present

WORK WITH THE DATA, P. 277

- These data fit the semiconservative model of DNA replication because the heavy strands were templates for new light strands; after one round of replication, all the DNA had one heavy (original) strand and one light (newly made) strand, and so was intermediate in weight.

Generation	Percent heavy DNA	Percent intermediate DNA	Percent light DNA
1	0	100	0
2	0	50	50
3	0	25	75
4	0	12.5	87.5

- After seven generations there would be about 1.5 percent intermediate DNA and 98.5 percent light DNA.
- In the first generation, the bands would be the same as in Figure B: all intermediate. In the second

generation, 1/2 would be intermediate and 1/2 heavy. In the third generation, 1/4 would be intermediate and 3/4 heavy. In the fourth generation, 1/8 would be intermediate and 7/8 heavy.

4. In a conservative model, the first generation would be 1/2 heavy, 1/2 light; the second generation 1/4 heavy, 3/4 light; the third generation 1/8 heavy, 7/8 light; and the fourth generation 1/16 heavy, 15/16 light. In a dispersive model, the first generation would be all intermediate; the second generation all half-way between intermediate and light; the third generation all half-way between the second generation peak and light; and the fourth generation all half-way between the third generation peak and light.

FIGURE QUESTIONS

Figure 13.6 Hydrogen bonds occur between the bases on opposite strands, within base pairs. Covalent bonds occur between the atoms that make up nucleotides and between the nucleotides in a DNA strand. van der Waals forces occur between the flat bases that stack on top of each other within the double helix, stabilizing them in the stacking.

Figure 13.13 On opposite sides of the origin, the leading strand will be the lagging strand, and vice-versa.

Figure 13.17 Shortened telomeres are unstable. Also, without telomerase there is unreplicated DNA. For these two reasons, gamete-forming cells express telomerase.

Figure 13.19 Both PCR primers in the test tube and DNA replication primers in the cell act to begin DNA replication. However, PCR primers can be complementary to any DNA strand, whereas DNA replication primers bind only to the origin of replication.

APPLY WHAT YOU'VE LEARNED

1. It will take about 280 hours to complete the synthesis of the shortest DNA strand from one starting point. This is much longer than the 8 hours that the cell has to complete DNA replication, so no one can claim that DNA replication involves just one starting point. The results of the calculation suggest that multiple starting points must be involved in replicating a strand of DNA.
2. The results suggest that multiple starting points for synthesis are present in a single DNA molecule. The number of starting points corresponds to the number of radioactive bands. This result is consistent with the hypothesis made based on the calculations in Question 1.
3. The results suggest that DNA synthesis is bidirectional. This is shown by the presence of two dark patches running 180 degrees from each starting point of synthesis, followed by lighter patches indicating a period of dilution during the change from radioactive to nonradioactive thymidine. If DNA synthesis were unidirectional, we would see single dark patches followed by lighter patches to either the left or the right but not in both directions.
- 4.

Chapter 14

RECAP 14.1

1. A model organism is easy to grow and manipulate in the laboratory and has representative characteristic(s) common to a larger group of organisms (e.g., a mouse for mammals).
2. Srb, Horowitz, Beadle, and Tatum treated wild-type *Neurospora* with X rays to cause mutations. Strains that could not grow without the addition of an amino acid (argi-nine) were isolated. The strains were separately incubated without arginine but with intermediates along the proposed biochemical pathway that makes arginine. Growth in one of the intermediates meant that the mutation for that strain must occur in a gene encoding an enzyme that acts before that substance in the pathway. In this way, the collection of mutant strains led to identification of the intermediates in the pathway and their order, and ultimately to the enzyme that acts to convert each intermediate into the next.
3. Enzymes: 4 → 2 → 3 → 1 → 5
Compounds: C → F → E → D → G → T.

RECAP 14.2

1. The central dogma states that DNA is transcribed to RNA, which gets translated into protein, a process that is unidirectional.
2. In retroviruses, the genome is RNA. To replicate, the RNA is converted to a DNA copy, which is then transcribed into RNA. This violated the original central dogma in that the DNA-to-RNA conversion was thought to be unidirectional.

RECAP 14.3

1. If the code were just single letters (A or T or G or C), each "letter" would translate to one amino acid (41).

But there are 20 amino acids, so a single-letter code could not unambiguously identify all amino acids. A doublet code would create 16 possible codons (4²), not enough to uniquely identify all 20 amino acids. A triplet code using four letters has 64 unique possibilities (4³), more than enough for 20 amino acids and stop codons. The code is redundant (there is more than one codon per amino acid) but not ambiguous (a codon does not stand for more than one amino acid).

2. RNA polymerase binds to DNA at the promoter. The DNA is unwound to expose the bases. The enzyme has binding sites for substrates, the ribonucleoside triphosphates. The enzyme then adds nucleotides to a growing chain by complementary base pairing to template DNA.
3. DNA must be replicated exactly. Any error in DNA in a gene that encodes a protein will result in an error in the RNA that is transcribed from that DNA region. This could result in a different codon and therefore a different amino acid at that location in the protein. The protein's function may change. RNA is made in many copies. So an error in an RNA could result in an error in the protein translated from it, but since there are many more normal copies of that RNA, there would be plenty of the normal protein for normal function.

RECAP 14.4

1. At the 5' end, a "cap" of modified GTP is added. This facilitates binding of mRNA to the ribosome and protects the mRNA from hydrolysis by ribonucleases. At the 3' end a poly A tail is added, with 100-300 A nucleotides. This assists in export of mRNA from the nucleus.
2. snRNP particles bind to consensus sequences at the 5' and 3' splice sites on pre-mRNA in the nucleus. The two ends approach each other, mediated by the snRNPs. mRNA is cut first at the 5' end and then at the 3' end, releasing the intron. The two exons are then joined.
3. 192 amino acids would be encoded by 576 nucleotides. Add start and stop codons for a total of 582 base pairs in DNA. The DNA has extra base pairs for the promoter and terminator of transcription, introns, and a sequence for mRNA binding to the ribosome.

RECAP 14.5

1. rRNA acts as a scaffold for proteins to make the ribosome structure, with binding sites for tRNA. An rRNA has a nucleotide sequence region complementary to a region on mRNA so the two RNAs can bind and begin translation. An rRNA acts as the catalyst for peptide bond formation.
- 2a. 3'-TACGGGCCCAATTCTTAAAATTTTACT-5'.
 - b. The bottom strand is transcribed: It has sequences that are transcribed into start (AUG) and stop (UGA) codons in RNA
 - c. mRNA: AUGCCCGGGUUAAGAUAUUUUAAAUGA
Polypeptide: Met-Pro-Gly-Leu-Arg-Tyr-Phe-Lys
3. A polysome is formed when more than one ribosome is bound to mRNA at the same time. This can occur because ribosomes move along mRNA in a 5'-to-3' direction, translating as they go, much like a cafeteria line. Polysomes allow more proteins to be made at a given time from an mRNA.

RECAP 14.6

1. Signal sequences are translated to regions in a protein that bind to recognition molecules and/or receptors associated with a particular destination in the cell.
2. Post-translational modifications are made to specific amino acids at particular locations on a protein. The locations are determined by the three-dimensional shape of the protein, allowing an enzyme for the modification to bind to the amino acid at that location. So overall, the amino acid sequence of the protein determines which amino acids will be modified posttranslationally, and the amino acid sequence is determined by the genetic code and DNA sequence for the gene.

WORK WITH THE DATA, [P. 291](#)

1. 34105: gene *a* 33442: gene *b* 36703: gene *c*.
2. The mutant strains may have had some residual enzyme activity, allowing for growth.
3. Arginine is part of proteins and is essential for the tertiary structure of proteins. Replacing it with other amino acids is not possible.
4. The double mutant cannot do the reactions ornithine → citrulline and citrulline → arginine. So adding ornithine or citrulline does not allow growth, since arginine is not produced.

WORK WITH THE DATA, [P. 297](#)

1. Minus poly U mRNA: Charged tRNA does not bind to the codon at the ribosome, so no polypeptide can be made. Minus ribosomes: There are no locations for adjacent charged tRNAs to bind and also no peptidyl synthetase to catalyze peptide bond formation. Minus ATP: tRNA cannot get charged with amino acids, and mRNA cannot translocate along the ribosome. No polypeptides are made. Plus RNase: mRNA is destroyed. See Minus poly U mRNA, above. Plus DNase: All the components for polypeptide synthesis are present. Radioactive glycine instead of phenylalanine: Charged glycine tRNA binds to mRNA codon

- GGU, GGA, GGG, or GGC. These codons are not present in the poly U mRNA, so no radioactive polypeptides are made. Mixture of 19 radioactive amino acids minus phenylalanine: Charged tRNAs are made, but their codons are not present, so no polypeptides are made.
- The data show that RNA (poly U) was essential for protein synthesis, since its absence resulted in no protein synthesis.
 - According to the genetic code (see [Figure 14.5](#)), UUU is the codon for phenylalanine. The other amino acids were not added to protein in the poly U experiment because only the UUU codon was present.

FIGURE QUESTIONS

[Figure 14.2](#) Prokaryotic cells lack a nucleus, so transcription and translation are not spatially separated.

[Figure 14.4](#) Both RNA synthesis and DNA replication require a polymerase enzyme that binds to DNA; the DNA must unwind to expose the bases; the new polymer is complementary to a template strand; and the substrates are nucleoside triphosphates.

[Figure 14.12](#) The chemical forces that hold the molecules of the ribosome together include hydrogen bonds, ionic attractions, and hydrophobic interactions. These can be disrupted by heat or detergent.

[Figure 14.15](#) If there is no stop codon, translation continues because there are more nucleotides at the end of mRNA past the stop codon location. The protein is not properly released from the ribosome.

[Figure 14.17](#) A protein with no “address” stays in the cytoplasm.

APPLY WHAT YOU’VE LEARNED

- Leu-1* is a mutation in the protein catalyzing step C. The product of this step (α -ketoisocaproate) is the first in the pathway able to overcome blockage in this mutant; therefore, *Leu-1* must be a mutation in the enzyme at step C. *Leu-2* is a mutation in the protein catalyzing step B. The product of this step (3-isopropylmalate) is the first in the pathway able to overcome blockage in this mutant; therefore, *Leu-2* must be a mutation in the enzyme at step B.
- The mutant cells carrying the *Leu-1* mutation are deficient in enzyme C but carry the wild type enzyme B. The mutant cells carrying the *Leu-2* mutation are deficient in enzyme B but carry the wild type enzyme C. Therefore, when the two cells fuse, the diploid cell contains one copy of wild type enzyme B and one copy of wild type enzyme C, which restores the wild type phenotype.
- The table summarizes the predicted enzyme activities:

Enzyme	Predicted enzyme activity		
	<i>Leu-1</i> (haploid)	<i>Leu-2</i> (haploid)	Fused cells (diploid) <i>Leu-1, Leu-2</i>
A	Wild type	Wild type	Wild type
B	Wild type	Wild type	Wild type
C	Wild type	Wild type	Wild type
D	Wild type	Wild type	Wild type

- One mutant strain is affected in the gene encoding the α subunit and the other mutant strain is affected in the gene encoding the β subunit. Thus, haploid cells cannot produce a functioning $\alpha_2\beta_2$ enzyme because these cells have only one copy of each gene, one of which is normal and one of which is not. Diploid cells, however, have two copies of each gene with one normal gene for α supplied by one of the mating pair and one normal gene for β , supplied by the other of the mating pair. The presence of a copy of a normal gene for each subunit allows the diploid cells to produce normal polypeptide chains of α and β , which associate to form a functional $\alpha_2\beta_2$ enzyme.

Chapter 15

RECAP 15.1

- Point mutations that cause phenotypic changes could have resulted in a different amino acid in the encoded protein that consequently changes a protein’s function; changed a promoter so a gene’s expression is significantly altered; or created a stop codon that terminates expression prematurely, resulting in a shorter nonfunctional protein. Point mutations that are phenotypically silent may arise in codons where redundancy ensures no amino acid change; cause codon changes that result in amino acid changes that are not significant to protein function; or occur in noncoding regions of DNA, such as introns.
- See [Figure 15.4](#). Deletions are missing part of a chromosome; duplications have an extra copy (or copies) of a chromosomal region; in inversions, a chromosome region is out of sequence; and in translocations, a piece of one chromosome breaks off and attaches to another chromosome.
- Spontaneous mutation occurs without an external agent causing it. Example: tautomeric shift of A, so that at DNA replication A base-pairs not with T but with C. In an induced mutation, an environmental agent

changes DNA. Example: nitrous acid deaminates C to U, so that at DNA replication, instead of C pairing with G, it is U pairing with A.

4. C can be methylated to 5-methylcytosine. When deaminated spontaneously or by a mutagen, this base forms T. This is a normal base and is not removed by DNA repair. Other base changes are repaired.

RECAP 15.2

- 1a. The amino acid sequence produced by the mutant allele is Leu-Ile-Ser-Ile-Ala. This is a missense mutation.
 - b. The mutation replaces proline with serine. Proline is a nonpolar amino acid that is usually part of bends or loops in a protein; serine is a polar amino acid with a smaller side chain. The mutation is likely to affect enzyme activity because it is likely to affect protein structure.
2. Simply having a particular genetic mutation is not sufficient to lead to cancer. There are other genetic and environmental factors that may be involved in developing breast cancer. For example, a person can have a mutation in a different gene for DNA repair, such that it takes over the functions that are lost by the *BRCA* mutation.
3. The symptoms occur only if there are a large number of repeats of the CGC sequence in the promoter region of the *FMR1* gene, so that they disrupt expression of the gene. Family members may carry the mutation but not show symptoms because the mutation contains a low number of repeats rather than a high number.

RECAP 15.3

1. Direct DNA sequencing of the cystic fibrosis gene could be done. A person who is a carrier will test positive for both the normal and the mutant alleles.
2. Mapping a disease-causing mutation can be done by linkage analysis. A polymorphic DNA marker such as an STR can be linked to the occurrence of a disease in many patients. This means that the marker must lie on the chromosome near the mutant disease-causing gene. DNA sequencing can then isolate the gene involved. From the gene sequence or genetic technology, the protein encoded by the gene can then be isolated and its function described. So genotype precedes phenotype.

RECAP 15.4

1. DNA analysis can be done on any tissue at any time in the life cycle of an individual. In addition, heterozygotes can be detected. Phenotype analysis by enzyme activity requires gene expression in an accessible tissue at a certain time and place. In many cases, heterozygotes cannot be detected.
2. A patient's DNA could be tested to see if it hybridizes to sequences of the mutant β -globin gene. If it did, this would mean that the patient carries the mutation, and no further sequencing of the patient's DNA would need to be done to verify this.

RECAP 15.5

1. Metabolic inhibitors block important chemical transformations in cancer cells. An inhibitor may either block the accumulation of a harmful substance or block cancer-specific transformations to harmful substances.
2. In vivo gene therapy inserts the wild-type form of a gene that is mutated or abnormally expressed in tissues of a person with a genetic disease or other disease. Typically a virus is used to deliver the gene, and the DNA either inserts into the host chromosome or stays outside the cell nucleus in a virus that does not replicate. An example is adding a gene for glutamate decarboxylase to the brains of patients with a neurotransmitter deficiency in Parkinson's disease (see Figure 15.19).
- 3a. The mutation that leads to PKU is rare in the human population; most people do not have the harmful allele, and the highest probability is that the father is homozygous normal. Because the mother has PKU (she is homozygous mutant), the developing fetus is heterozygous.
 - b. High levels of phenylalanine cause brain damage. If the mother's phenylalanine levels were too high, the baby would be born with brain problems.
 - c. The woman should be on a phenylalanine-restricted diet.

WORK WITH THE DATA, P. 329

1. In the three families, breast cancer occurred in two-thirds of the patients early in life, suggesting that the cancer was hereditary.
2. All three mutations were present only in the breast cancer patients. In Families A and B, the two point mutations may have caused codon mutations and a different amino acid in each case in the *BRCA1* protein, causing it to be nonfunctional. In Family C, the deletion was 11 base pairs, which resulted in a frame-shift mutation and meant that the codons after that mutation were read incorrectly. This caused massive changes in amino acid sequence and a nonfunctional *BRCA1* protein.
3. *BRCA1* is active in breast, ovary, and thymus tissues. So mutations would also be expressed there. Since *BRCA1* is involved in DNA repair, all three of these tissues would experience poor repair, leading to additional mutations that can cause cancer.

FIGURE QUESTIONS

Figure 15.1 Silent mutation, because the genetic code is redundant (many mutations do not change the amino acid translated) and because many amino acids in a protein are not essential for the activity of the protein (e.g., do not affect the active site).

Figure 15.3 Chromosomal mutations can be detected by staining dividing cells with dyes specific for each chromosome. Stained chromosomes can then be identified, and missing pieces or translocated pieces can be observed. Inversions can be detected by a special method called banding, whereby dyes on chromosomes produce banding patterns instead of colors. In this case, a reversal of bands can be seen.

Figure 15.13 The advantage of a genetic ID would be to predict future propensities for diseases and possibly act to prevent them, and to identify a person in an accident, war, or crime (this is already done with soldiers and people in federal prisons). A disadvantage would be that in the wrong hands there could be an invasion of privacy. Genetic markers would need to be used with caution as they are not necessarily predictive; environmental factors often play a role in disease as well. While a federal law in the United States prohibits using genetic data to discriminate against people applying for insurance and employment, the concern remains that genetic data may nevertheless influence decision makers in these and other arenas.

Figure 15.14 Chromosome linkage analysis involves actual crosses and is done by analyzing the results of recombination between alleles. DNA linkage analysis is done on single chromosomes by retrospective analysis of mating. Chromosome linkage analysis examines phenotypes, whereas DNA linkage analysis examines genotypes (DNA).

APPLY WHAT YOU'VE LEARNED

1. Person 1 is heterozygous, with one normal allele and one mutant allele. The normal allele translates to the amino acids: Pro-Trp-Thr-Gln-Arg-Phe. The mutant allele has a stop codon at position 4 in the mRNA (a nonsense mutation): Pro-Trp-Thr-(stop), and the polypeptide is short, only 38 amino acids instead of 146. So this globin would not be functional. Person 2 is heterozygous, with one normal and one mutant allele. In this case, the mutant allele is a deletion of the first T in the second codon. This causes a frame shift: Pro-Gly-Pro-Arg-Gly-Ser..., and the resulting polypeptide has a very different sequence and is most likely nonfunctional.
2. One example is a mutation that affects the promoter such that RNA polymerase cannot bind to initiate transcription. Another example is a mutation that affects mRNA splicing sites in the DNA that leads to abnormal deletions or insertions in the mature mRNA transcript.
3. The couple has a 1 in 4 chance of producing a child who is homozygous with two normal alleles, a 1 in 2 chance of producing a child who is heterozygous with one normal allele and one mutant allele, and a 1 in 4 chance of producing a child who is homozygous with two mutant alleles. A child with two mutant alleles would suffer severe anemia and would have to receive regular blood transfusions throughout life.

Chapter 16

RECAP 16.1

1. The cell could reduce the transcription of the Xase gene, hydrolyze Xase mRNA, prevent Xase RNA translation, hydrolyze Xase protein, or inhibit Xase protein.
2. In the presence of lactose, the promoter is exposed and RNA polymerase binds to begin transcription. In the absence of lactose, the promoter is occupied by the repressor and there is no transcription.
3. Sigma factors direct RNA polymerase to bind to recognition sequences at certain promoters. If several

promoters of genes with related functions (e.g., heat shock response) have the same recognition sequence, transcription of those genes will occur at the same time and rate.

4. To keep a constant, low-level expression of repressor protein, the regulatory gene would have to have an inefficient promoter, and synthesis of the repressor would be constitutive.

RECAP 16.2

1. General transcription factors bind to the promoter and to RNA polymerase in a complex to direct RNA polymerase to the promoter to initiate transcription and locally denature DNA so that the template strand is available for base pairing during RNA synthesis. Specific transcription factors bind to specific promoters or promoters with recognition sequences. Other transcription factors bind to enhancer sequences that can be far from the actual promoter and induce DNA to bend to attract the rest of the initiation complex for transcription.
2. Proteins such as transcription factors fit into the DNA double helix by structural motifs, and their amino acids may form hydrogen bonds with bases on the interior of the double helix. The sequences of amino acids (proteins) and of bases (DNA) are specific so that only certain proteins bind to certain DNA sequences.
3. In response to a signal from the environment or within the cell, a specific transcription factor is made and/or translocated into the nucleus where it binds to a recognition sequence in DNA at the promoters of target genes. This binding attracts the initiation complex for transcription, so multiple genes are activated.

RECAP 16.3

1. In the bacteriophage: Phage DNA is injected into the host cell. Early phase genes are transcribed at phage promoters by using DNA sequences similar to those of the host cell (positive regulation). This leads to early protein that binds to host promoters to shut them down (negative regulation). Other early proteins lead host RNA polymerase to transcribe middle and late phage genes (positive regulation). In HIV: HIV RNA is injected into the host cell. HIV reverse transcriptase is activated to make cDNA and integrase to splice cDNA into the host chromosome (positive regulation). Later, host RNA polymerase binds to HIV promoters to make HIV mRNAs (positive regulation). HIV tat protein acts as an anti-terminator for the transcription of HIV genes integrated into the host genome.
2. HIV infection, cDNA formation and integration would occur as normal. Viral genes would be expressed and a large precursor protein would be made. But it would not be cut into separate viral proteins. HIV particles would not be packaged or released from the cell.

RECAP 16.4

1. Histone proteins are positively charged and bind to DNA, generally blocking transcription. Acetylation of histones neutralizes the positive charge and thus the histones do not bind to DNA as tightly, which opens up the chromatin structure for transcription. By contrast, histone deacetylation removes acetyl groups, restoring positive charges on histones so transcription is repressed.
2. See the opening story and Investigating Life: Gene Expression and Behavior (p. 351). The behavioral environment appears to alter DNA epigenetically by increasing DNA methylation at promoters in genes in brain tissues, thus changing the rate of gene transcription.
3. X chromosome inactivation is shown in [Figure 16.16](#). The *Xist* gene on the X chromosome is transcribed to make a short RNA that binds to the rest of the X chromosome, inhibiting transcription of the other genes. Chromosome proteins bind to the inactive X chromosome, causing heterochromatin to form and inhibiting gene expression. X chromosome inactivation is believed to occur in order to balance the expression of X-linked genes between males (XY) and females (XX) since the Y chromosome does not usually contain X-linked genes.
4. You could sequence the relevant genes of colorectal cancer cells and look for mutations that lead to aberrant function, then isolate the proteins involved and determine that their functions are indeed abnormal. To show epigenetic silencing, you might sequence the promoters of the genes and look for epigenetic changes (e.g., cytosine methylation, which would be increased if there were transcriptional silencing). Then you could examine the tumor cells to see if the active proteins were there but in small amounts.

RECAP 16.5

1. miRNAs and siRNAs can bind by base pairing to target mRNAs and prevent their translation because tRNA cannot bind; or the inhibitor RNAs can bind to pre-mRNA in the nucleus and lead to its hydrolysis by RNase; or the inhibitor RNAs can bind to DNA at the transcription site and block RNA polymerase from working for transcription.
2. mRNA can fold back on itself by hydrogen bonding of complementary bases, forming looped structures. These structures can bind to proteins that then inhibit translation at the ribosome.
3. The proteasome binds to proteins that are targeted with ubiquitin for breakdown. Within the proteasome are proteases that hydrolyze targeted proteins.

4. On average, a human gene can form at least four different mRNAs by alternative splicing. Each of these mRNAs is translated to a unique protein. So the number of different proteins is much greater than the number of genes.
5. miRNAs targeted to activated oncogenes will block the translation of target mRNAs that would make proteins that otherwise stimulate cell division.

WORK WITH THE DATA, P. 351

- 1a. mRNA was measured in the heads because gene expression in the brain determines whether a honey bee will be a worker or a queen.
- b. The level of inhibition of DNMT mRNA was about 60 percent after 48 h. This is good but not perfect inhibition. So some DNMT mRNA probably remained.
2. The reduction of DNA methylation was about 20 percent. So some 5-methylcytosine remained.
3. In the controls, about 23 percent of the larvae developed into queens. But in the larvae that had reduced DNA methylation, about 72 percent developed into queens. This is a remarkable shift given that DNMT mRNA and DNA methylation were reduced but not as much. There must be a threshold for methylation, above which gene expression is affected.

FIGURE QUESTIONS

Figure 16.1 Yes. There can be multiple binding sites for regulatory proteins at the promoter region.

Figure 16.7 An advantage of the nucleus is compartmentation—the separation of transcription/processing and translation. This allows for finer regulation of gene expression. Also, the nucleus is protected from nucleases in the cytoplasm, which might hydrolyze mRNA and reduce its lifetime as it is made.

Figure 16.13 Lysogeny is a term used for bacteriophage to describe the integration of the viral genome into the host cell for a period of time. Although the term is not used for eukaryotic viruses, HIV does integrate its genome as cDNA and so could be called lysogenic.

Figure 16.14 5-methylcytosine mutations (deamination) are not repaired. So locations with 5-methylcytosine will tend to accumulate mutations and their potential to regulate transcription will vary.

Figure 16.17 7

APPLY WHAT YOU'VE LEARNED

1. An inhibitor of DNA methylation restores tumor suppressor activity in the cancer cells. The same effect is observed with an inhibitor of histone deacetylation. These results suggest that both DNA methylation and histone deacetylation operate to shut down expression of genes that suppress tumor growth.
2. The data show that inhibitors of both histone deacetylation and DNA methylation act together with greater effect than either inhibitor alone. This suggests that some gene expression is inhibited by DNA methylation, some by histone deacetylation, and some by both processes. In this last group of genes, both inhibitors must be required to release the genes from being silenced.).
3. Gene 1 can be reactivated by either inhibitor, but Gene 2 can be reactivated only by a combination of the two inhibitors. For Gene 1, the extent of DNA methylation and histone deacetylation may not be great. In this case, either DNA demethylation or histone acetylation may tip the balance just enough to alter the nucleosome to allow access of RNA polymerase to bind to the promoter and express the gene. In the case of Gene 2, RNA polymerase may be prevented from binding to the promoter for two reasons: the promoter site could be heavily methylated and histones could also be deacetylated, thus preventing loosening of the nucleosome to expose the promoter region. Therefore, for Gene 2 both DNA methylation and histone deacetylation must be inhibited for expression to be restored.

Chapter 17

RECAP 17.1

1. Before sequencing, a long DNA molecule is cut into many fragments. These cuts are random (i.e., they are made at different random locations). The overlaps are important in arranging the final sequence. If there were only one type of cut, aligning the final sequence would not be possible. The sequences of the fragments are arranged by computer using the overlaps as a guide.
2. Open reading frames are recognized by the presence of a promoter sequence, triplet start and stop codons, transcription termination sequence, and recognition sequences at the beginning and end of introns. The reading frame gives the promoter sequence (signal for when and where the gene is expressed) and the sequence of amino acids of the protein (an indication of its function).
3. Comparative genomics is the study of DNA sequences across different organisms. Similar sequences detected in different DNA samples may help reveal the function of a protein (when a sequence matches that of a known protein in another organism), the identity of a species known only by its DNA (metagenomics), and evolutionary relationships. The gene that influences the relative sizes of dogs, for

example, was identified by comparative genomics.

RECAP 17.2

1. The following characteristics of prokaryotic genomes are essential for organisms that exist in a rapidly changing environment and must adapt rapidly: (1) Small genomes can show large changes with a few mutations. (2) Plasmids allow individual cells to share genomic information rapidly. (3) Transposons shuffle gene locations and therefore the rate of gene expression, and they cause mutations that make evolution possible.
2. Transposons either splice out of the host chromosome directly and move to a different location, or they make a DNA copy that is inserted at a different location, leaving the original transposon in place.
3. One could take a sample of belly-button "lint" and extract DNA from it, then do PCR to amplify sequences that are prokaryotic and identify the species present. If this were done for many people, there would presumably be a unique set of species abundances for each person.

RECAP 17.3

1. Genes for tissue formation are present in *C. elegans* but not in yeast.
2. Gene families allow for evolutionary "tinkering." If there are several copies of a gene in the genome, mutations in one copy of the gene may temper a harmful effect of the wild-type copies of the gene. If the mutations are beneficial, they will be selected for.
3. In some tissues, such as the egg cell, there is a need for massive protein synthesis (after fertilization) and therefore a need for a lot of ribosomes. The rate of transcription of the rRNA genes is not sufficient to meet the cell's need for ribosomes, so there are multiple copies of the gene.
4. The four plants exist in different environments. For example, corn grows in drier and cooler regions than rice. Mutations of the basic plant genome allowed plants that carried them to adapt to the different environment to survive and reproduce.

RECAP 17.4

1. Each human gene has several introns. Alternative splicing of pre-mRNA from a single gene can result in different mRNAs and therefore different proteins.
2. The human genome sequence has haplotypes that are linked to differential sensitivity to a drug. If the patient's DNA is isolated and amplified, a classification with regard to the haplotypes can be made, and whether the patient will respond to a particular drug can be determined.

RECAP 17.5

1. The proteome is analyzed by identifying large numbers of proteins using two-dimensional gel electrophoresis and by identifying fragments of proteins by mass spectrometry.
2. Patterns of metabolites correlate with different physiological states. The simplest example of why it would be useful to have a database of primary and secondary metabolites involved in human metabolism might be the high level of blood glucose that is associated with diabetes. Most diseases are more complex than this. Diagnosis may be helped by a pattern of metabolites in the metabolome.

WORK WITH THE DATA, [P. 363](#)

1. There was a 4.4 percent change in DNA sequence between the two cat genomes in 10.8 million years. This indicates a rate of change of 0.4 percent per million years. By comparison, the rate of change between the human and gorilla genomes was 0.6 percent per million years, or 50 percent faster.
- 2a. 14,425 gene families are shared by all the mammalian genomes examined.
 - b. 103 are unique to the tiger and domestic cat genomes; 231 are unique to the human and mouse genomes.
 - c. Over 90 percent of the mammalian genome is common to all mammals. Relatively few gene families are unique to each kind of mammal examined.
3. The tiger is a hunter, and its genome reflects this, with genes for smell, signaling and digestion.

FIGURE QUESTIONS

Figure 17.4 A retrovirus infects a cell and makes a cDNA copy of its genome. The cDNA is inserted into the host cell by the action of viral integrase. The cDNA is carried along with the host chromosome as the cell divides. Through recombination, the cDNA adds a gene for excision. It also adds adjacent genes and is able to move about the genome.

Figure 17.6 No. Protein-coding genes represent only a small fraction of eukaryotic genomes. Increasing size could include genes that do not encode proteins as well as repetitive sequences.

Figure 17.10 In both processes a protein structure is moving along a nucleic acid. In the polysome, the ribosome moves along mRNA; in rRNA synthesis, RNA polymerase moves along DNA. In both processes a polymer product is made: in the polysome the product is a polypeptide, and in the rRNA the product is RNA. The two processes are similar also in having a "cafeteria" system in which multiple polymers are made at the same time.

APPLY WHAT YOU'VE LEARNED

1. For SNP 5689, individuals with genotype AA have the highest concentrations (and thus the slowest metabolism) of Calm. Individuals with GG have the lowest concentrations (fastest metabolism) of Calm. Heterozygotes are intermediate. For SNP 8835, AA homozygotes have the lowest concentrations (fastest metabolism), CC homozygotes have the highest concentrations (slowest metabolism), and heterozygotes are intermediate. For SNP 11286, the heterozygotes have the highest concentrations (slowest metabolism). The two homozygotes have roughly similar concentrations and thus similar metabolisms.
2. Because AA individuals at this SNP have a slower metabolism of the drug than do GG individuals, the AA individuals should receive a lower dose.
3. AA homozygotes have the slowest metabolism and GG homozygotes have the fastest. Thus one would expect that the enzyme encoded by the A allele of the gene would be less active than the enzyme encoded by the G allele.
4. AA homozygotes have the fastest metabolism and CC homozygotes have the slowest. Thus one would expect that the inhibitor encoded by the A allele of the gene would be less active than the inhibitor encoded by the C allele.
5. Give the treatment mice the drug and leave others as the control. Prepare liver tissue from the treatment and the control mice. Use two-dimensional gel electrophoresis and mass spectrometry to identify differences in the proteins from the livers of treatment and control mice.

Chapter 18

RECAP 18.1

1. The sequences for recognition by a restriction enzyme often occur near one another on the opposite strands of DNA. For example,
5'....GAATTC....3'
3'....CTTAAG....5'
The top and bottom strands have the same 5'-to 3'-sequence. A restriction enzyme recognizes this and cuts between the G and A:
5'....GAATTC....3'
3'....CTTAA G....5'
Note that the cuts are staggered, not directly opposite each other.
2. DNA from two genetically different strains of bacteria, each carrying a different antibiotic resistance gene, was cut with the restriction enzyme *EcoRI* and then spliced together using DNA ligase.

RECAP 18.2

1. GFP reporter: all cells alive. Antibiotic resistance: most cells dead and only a selection alive. GFP reporter: need only a UV lamp to see the reporter gene product. Antibiotic resistance: need to alter growth medium and wait until nonselected cells are dead to identify cells with the vector.
2. The sequence would be: d, e, a, b, c.

RECAP 18.3

- 1a. This involves tissue-specific gene expression, so use RT-PCR, which is a “snap-shot” of the mRNAs in the cell at a given time and can identify the amylase mRNA.
b. This calls for genomic analysis, so use a genomic library and identify the amylase gene in the strains.
2. All cellular RNA is isolated and cDNA copies of the RNAs are made using reverse transcriptase. Primers for DNA replication are made for the two ends of the DNA for the specific gene whose expression is to be studied. Then a PCR procedure is carried out using these primers. The degree of amplification from these primers is proportional to the specific cDNA target, which in turn is proportional to the amount of the specific RNA in the original cell extract.
3. Synthetic DNA can be used to make a probe for hybridization to identify a genotype, as in genetic screening for human diseases. Mutations in the DNA can be used to detect mutations in patients.
4. Both tissues express some identical genes that are involved in cellular activities, such as energy metabolism (e.g., genes encoding enzymes in the citric acid cycle) and informational functions (e.g., making rRNA). The tissues will differ in tissue-specific mRNAs. For example, the brain makes proteins needed for electrical activity and communication between cells, while the pancreas makes the hormone insulin. But note that all tissues have the same DNA sequences—all of them.

RECAP 18.4

1. Antisense RNA and siRNA act to prevent translation by binding to mRNA by base pairing and leading to its breakdown in the cytoplasm.
2. Germinate pea seeds and extract RNA from the embryos at different times. Make cDNA from the mRNA's

and hybridize the cDNA's to a library of genes from the entire plant genome. The extent of hybridization to the genes will indicate differences in which genes are expressed.

3. CRISPR has the additional advantage of specifically changing the nucleotides in genes, that is, introducing mutations or reversions.

RECAP 18.5

1. Expression vectors have restriction site(s) for insertion of genes, a DNA replication origin, a tissue-specific active promoter for the proposed host cell, and often a sequence for signaling the protein to be sent to the extracellular medium for isolation in the lab.
2. Biotechnology is faster (one instead of many generations of breeding) and specific (only a single gene is introduced, instead of many during selection for a complex characteristic).
3. Because the bacterium *E. coli* normally lives in the human intestine, there was a danger that lab strains resistant to multiple antibiotics might infect people. Furthermore, there may have been concern that the genes of antibiotic-resistant strains might recombine with the genes of normal strains, resulting in the development of multiple-antibiotic-resistant strains. Another concern was that bacteria could be used to harbor genes encoding toxins as biological warfare agents. To alleviate these concerns, the host *E. coli* strains were developed with multiple mutations so that they would require a special lab environment to survive. For example, mutations in genes for the synthesis for vital metabolites were introduced so the bacteria would need to be supplied with metabolites that the human intestine does not provide. With no TPA there was no clot dissolution, but with TPA there was dissolution. Labmade TPA was somewhat superior to natural TPA both in terms of the rate of clot dissolution and the final percentage of dissolution.

WORK WITH THE DATA, P. 393

1.

With no TPA there was no clot dissolution, but with TPA there was dissolution. Lab-made TPA was somewhat superior to natural TPA both in terms of the rate of clot dissolution and the final percentage of dissolution.

2. Again, lab-made TPA was somewhat superior to natural TPA in dissolving clots in the rabbits. A comparison could be made between the final percent of dissolution using a *t*-test.

FIGURE QUESTIONS

Figure 18.2 DNA ligase is needed for the formation of strong covalent bonds to link the DNAs.

Figure 18.4 Cells with GFP reporter plasmids are not killed. This means that the cell or organism with the plasmid can be grown directly, without killing other cells. Also, it means that live organism experiments, following the fates of cells with recombinant DNA over time, are possible.

Figure 18.10 DNA sequences that encode posttranslational modifications of the enzyme would be necessary, specifically the signal sequence that is involved in targeting the enzyme to lysosomes.

Figure 18.13 Synthetic cells could be programmed to make natural molecules with new properties such as antibiotics with altered structures and targets, or plastics that are biodegradable, or fuels.

APPLY WHAT YOU'VE LEARNED

1. The daughters all are homozygous for the transgene. Under Mendelian expectations, the daughters should be heterozygous.
2. The male offspring inherit their X chromosome from their mother. The female parent in this cross lacked the transgene.
3. Because the F1 females are homozygous for the transgene, they should produce male offspring that all have the transgene, regardless of their mate's genetic makeup. Males have only one copy of the X

chromosome. These males should then produce daughters that are all homozygous for the transgene. The cycle would continue, yielding more and more flies with the transgene.

4. Additional transgenes that inhibit malaria transmission would be needed. In actual practice, there are genes that cause the mosquitoes to be resistant to *Plasmodium*. Thus the mosquitoes would still bite humans, but the likelihood that they would transmit malaria would be reduced.
5. Because the technology is very powerful and CRISPR can theoretically be used in just about any organism, there is a legitimate concern about accidental release of the construct. Laboratory safety protocols are vitally important. The researchers have used stringent containment procedures in accordance with approval from their institutions.

Chapter 19

RECAP 19.1

1. Transplantation experiments with amphibian embryos showed that in the early amphibian embryo, cell fate is not yet determined and the environment in which a cell is placed can result in determination. In the later embryo, cell fate has been determined and the environment has no effect.
2. Stem cells in adult body tissues are typically multipotent, while stem cells in the embryo are typically pluripotent.
3. One could analyze mRNA in egg cells, in the parent differentiated cells, and in the reprogrammed cells. This could be done by reverse transcriptase PCR or by gene expression arrays.
4. In animals, cloning has been used to reproduce valuable organisms and increase populations of rare species. In humans, reproductive cloning could be used by couples who want offspring that are genetically related to one or both of them but who cannot produce eggs or sperm. It could allow a lesbian couple to have children that are genetically related to them or gay male couples to have genetically related offspring (using a surrogate mother to carry the child). It could allow a couple to have a child who is genetically the same as a child who is dying.

RECAP 19.2

1. Unequal distribution of a cytoplasmic component in the fertilized egg can result in only one of two daughter cells receiving the component after cell division. This asymmetry can be maintained by the cytoskeleton. It can mean that only one of the two cells will express certain genes, resulting in a difference in cell fate determination.
2. The anchor cell would not be able to send a differentiation signal to the overlying surface tissue, so the latter would not develop into the vulva.
3. The *p21* gene would be activated and the cell cycle would be blocked; in the presence of other factors, muscle cells would form.

RECAP 19.3

1. Organ identity genes specify different organs of the flower in plants. They are identified by loss-of-function mutations (mutations that result in a missing organ) or gain-of-function mutations (a promoter for the gene specifying one organ can be artificially spliced to a gene specifying a different organ, causing the latter gene to specify the first organ). Which particular organ will be generated depends not just on the expression of a single organ identity gene but on the combination of the expression of other genes. For instance, the whorl that generates petals (whorl 2) and the whorl that generates stamens (whorl 3) both express class B genes. The difference between these whorls lies in the other organ identity genes that they also express, with whorl 2 also expressing class A genes and whorl 3 also expressing class C genes.
2. A mutation that caused expression of class A genes instead of class C genes would lead to an AB combination instead of AC, and petals would develop instead of stamens.
3. All neuronal precursors might undergo apoptosis, and no neurons would form. The Hunchback protein gradient would not form properly, and the embryo would not establish its anterior–posterior axis.

RECAP 19.4

1. Substituting the fruit fly genetic switch for eye formation in the mouse embryo for the mouse genetic switch still resulted in eye formation in the mouse, and vice versa. This indicates that the genetic switches for development are conserved in evolution.
2. BMP4 is involved with cartilage development.
3. The observations are consistent with the hypothesis that there has been selection in some human populations for mutations of the enhancer that controls expression of the glycoprotein in red blood cells. This genetic change would be expected to have a selective advantage in human populations that are exposed to malaria at high levels, because the mutation confers greater resistance to malaria in humans who carry it.

RECAP 19.5

1. The developmental gene *Dll* controls the formation of legs in arthropods. Insects have three pairs of legs on their three thoracic segments, whereas centipedes have many legs on both thoracic and abdominal segments. In insects, the expression of *Dll* is repressed by the gene product of *Ubx*. *Ubx* is expressed in the abdominal segments of all arthropods, but it has different effects in different species. In centipedes, *Ubx* is co-expressed with *Dll* to promote the formation of legs. During the evolution of insects, a mutation in the *Ubx* gene sequence resulted in a modified Ubx protein that represses *Dll* expression in abdominal segments.
2. Marine sticklebacks have bony structures that protect them from predatory marine fish. In freshwater sticklebacks, these structures are not prominent. The differences are due to the expression of a developmental regulatory gene, *Pitx1*, which encodes a transcription factor normally expressed in regions of the developing embryo that in marine sticklebacks form the head, trunk, tail, and pelvis. However, in several freshwater stickleback populations, the *Pitx1* gene is no longer expressed in the pelvis, and spines do not develop. This same change in regulatory gene expression has evolved to produce similar phenotypic changes in several independent populations and is an example of parallel evolution.

FIGURE QUESTIONS

Figure 19.8 Yes, If the cell on the right of the figure had fewer receptors but the same exposure to inducer, it might have less activation of transcription.

Figure 19.16 If *Ubx* was expressed in all segments, the expression of the wing-forming gene would be inhibited and halteres would form.

Figure 19.19 If Gremlin was blocked in the developing feet of duck embryos, there would not be apoptosis between the digits and so chickenlike feet would form.

Figure 19.20 *Drosophila* with the centipede *Ubx* gene would grow legs from abdominal segments.

WORK WITH THE DATA, P. 404

1. In an RCT, the only difference between treated and untreated subjects is the response to the variable under investigation. Genetic and other differences between experimental and control groups are assumed to be randomized and equal between the groups.
2. The difference in the score for lameness in the stem cell group at 60 days was -1.11 . This is greater than the difference in the experimental group (-0.33). So there was more improvement in the stem cell group. A statistical test to show the significance of the differences would be the *t*-test.
3. Plot with Excel. The beneficial effect of stem cell treatment was evident after 30 days.

APPLY WHAT YOU'VE LEARNED

1. The two species differ with respect to how long the transcription factor expression remains high, with the duration of high expression being longer in Species 1. Thus this difference in timing is an example of heterochrony. A reasonable hypothesis is that the morphological difference between the species arises from differential timing of the transcription factor's expression; specifically, a longer period of high expression (as in Species 1) leads to longer bristles.
2. A direct test of the hypothesis would involve experimental manipulation of the transcription levels in the two species. Increasing the duration of high expression of hairball in Species 2 should result in a bristle size more like that of Species 1. Decreasing the duration of high expression of hairball in Species 1 should result in a bristle size more like that of Species 2.
3. The differences in the presence of bristles in the other segments are likely due to the expression of hairball in those segments. Given that hypothesis, the prediction is that expressing hairball appropriately in those other segments should result in bristles in those segments in Species 1 and 2. This is an example of heterotopy.
4. You could express the Hox gene from Species 3 in Species 1 and Species 2 and eliminate the

expression of their normal Hox gene. If the differences in the Hox gene are responsible for the bristle pattern difference, then the flies of Species 1 and Species 2 with Species 3 Hox expression should have a bristle pattern like that of Species 3. Similarly, expressing the Species 1 Hox gene in Species 3 should result in a Species 1 bristle pattern in Species 3.

Chapter 20

RECAP 20.1

1. In science, the word “theory” does not mean just a guess or an untested idea. Instead, theory refers to a well-tested body of knowledge that explains the facts that we observe in the natural world. The millions of observations biologists make of living and fossil organisms every year demonstrate the factual basis of evolution. We can observe changes over time in the extensive fossil record of the Earth, just as we can observe the process of evolution at work in living natural populations and in controlled laboratory experiments. Observing that evolution occurs, however, does not by itself explain how evolution occurs. “Evolutionary theory” refers to the body of knowledge about the processes of evolution and our models of how those processes work. For example, using mathematical modeling, a biologist can show that we expect all biological populations of a finite size to evolve by genetic drift. That does not mean, however, that other processes are not resulting in evolutionary change as well. Charles Darwin’s major contribution was to argue that the process of natural selection was a major factor in the evolution of populations of living organisms over time. That idea has been tested many thousands of times by many thousands of biologists since Darwin’s time, and natural selection has been repeatedly shown to be important in the evolutionary change that biologists have observed, and continue to observe, across life on Earth.
2. Although most individual bacteria would die upon exposure to an antibiotic, bacteria that could survive short-term exposure would multiply rapidly after the antibiotic treatment ended. Over time, the population of bacteria would evolve resistance to the antibiotic, as any mutations that allowed survival would increase in frequency. The full treatment is judged to be effective against virtually all the bacteria in the population. If no bacteria survive the full course of the antibiotic, then the population cannot evolve resistance. If the treatment is stopped short, then there is an increased likelihood that some of the bacteria (those with the greatest antibiotic resistance) will survive, and the population of bacteria will evolve increased antibiotic resistance.
3. Humans select traits in domestic plant and animal populations based on our interest in the trait, rather than on how it affects the natural reproductive rate or survivorship of the organisms. Many of the traits selected by humans would not be advantageous in wild populations. For example, humans have selected many cattle breeds for high body fat and high body weight. These traits result in large calves, which in turn result in calving difficulties for cows. Ranchers often have to assist in the birth of such calves, because the calf (and likely its mother) would often die without such assistance. In a natural population, there would be selection for smaller calf size and birth weight, which would increase the successful reproductive rate and survivorship.
4. Behaviors can respond to environmental cues that are predictive of future conditions, and these behaviors can be selected for if they are under genetic control. For example, day length becomes shorter as we move closer to winter, so individual mammals have a survival advantage if they respond to shortening days by going into hibernation. In this case, the environmental cue (day length) is predictive of future environmental conditions (the cold of winter). The traits exist in the present because these associations (as between shortening day length and the approach of winter) have existed for a long time.
5. Natural selection cannot act when there is no effect on the effective reproductive rate of the organism. Diseases such as Alzheimer’s usually occur long after the reproductive years have passed. As long as the disease does not affect the relative likelihood of the survival of the affected person’s offspring (as a result of reduced parental care, for example), we would not expect natural selection to lead to any reduction in Alzheimer’s disease in human populations.

RECAP 20.2

1. Mutations provide the genetic variation on which all the other evolutionary processes act.
2. Neutral traits (traits that confer neither an advantage nor a disadvantage) are free to increase or decrease in a populations by drift alone. In small populations, chance effects have a large role. If the difference in fitness between individuals is relatively small, and there are few individuals in a population, then which individuals survive and reproduce is likely to be a result of factors that do not relate directly to the fitness of the organism. Under these conditions, even some mildly deleterious traits are expected to become fixed in the population over short periods of time.
3. Self-fertilization reduces the frequency of heterozygotes but does not change the allele frequencies in a population. By contrast, sexual selection (nonrandom mating in preference for a particular phenotype) produces a directional change in the population. Hence, the population evolves.

4. A small population might be under strong selection for a particular trait that is favored locally. However, if there is extensive gene flow from neighboring populations where the particular trait is not favored, then selection for the trait in question will be overwhelmed by the gene flow from the surrounding populations.

RECAP 20.3

- 1a. Frequency of allele *a*: 0.60; of allele *A*: 0.40;
b. Frequency of genotype *aa*: 0.40; of genotype *Aa*: 0.40; of genotype *AA*: 0.20;
c. Expected frequency of genotype *aa*: 0.36; of genotype *Aa*: 0.48; of genotype *AA*: 0.16

2. $2pq = 2(0.2)(0.8) = 0.32$

Since the observed frequency of heterozygotes is lower than the frequency predicted by Hardy-Weinberg expectations, any of the following are reasonable explanations of this pattern:

- Toads from two or more adjacent subpopulations could be breeding in the same pond. The frequencies of alleles in each population may differ, resulting in high frequencies of different alleles in each subpopulation. In other words, the assumption of no gene flow has been violated.
 - Toads may not be breeding randomly within the population. For example, if closely related toads are more likely to mate with each other than with distantly related toads, then fewer heterozygotes would be expected in population (a form of inbreeding).
 - Heterozygous individuals may be at a disadvantage in the population (e.g., fewer heterozygotes may survive to adulthood). This would represent a violation of the Hardy-Weinberg assumption of no selection.
3. Presumably, the observed population is large enough to calculate that the low frequency of heterozygotes is significant. However, if the present generation of toads was produced by a small number of parents in the previous generation, then random effects of a small population size could explain the observed pattern.

RECAP 20.4

1. Stabilizing selection results in a reduction in variation within the population and an increase in frequency of the modal phenotype. Directional selection results in a change in the modal phenotype of the population in one direction. Disruptive selection results in a population with a bimodal distribution of phenotypes.
2. As shown in [Figure 20.13](#), mortality increases with both smaller and larger birth weight compared to the optimal birth weight of about 7.5 pounds. Significantly smaller babies are more likely to be premature or undernourished, and thus less likely to survive. Significantly larger babies may cause difficulties in delivery, putting both the baby and mother at greater risk and stress during childbirth. Thus, babies close to the modal birth weight are most likely to survive and grow into adults, thereby increasing the relative frequency of alleles for intermediate birth size in the population.
3. Almost any phenotype of an organism that differs markedly from its close relatives is likely the result of directional selection. Among the many thousands of possible examples, consider the long necks of giraffes, the long trunks of elephants, the great body size of whales, the large brain of humans, the great height of giant sequoias, and the large floating leaves of water lilies. Directional selection obviously can result in reduction in size as well, so also consider the tiny body size of hummingbirds compared to other birds, or the tiny leaf size of duck weed compared to other flowering plants. Undoubtedly, you can think of many other examples.

RECAP 20.5

1. The heterozygotes between the sickle-cell and normal alleles may have an advantage in defense against malaria. The normal allele may be able to function normally, whereas the sickle-cell allele provides protection against the malaria parasite.
2. A large population of humans could be tested for infection with malaria, and the frequency of infection, and the consequences of the infection, could be compared in people who do versus do not carry the sickle cell gene as heterozygotes. If the heterozygous individuals have an advantage in malaria resistance, we would expect them to exhibit lower infection rates or reduced effects of infection.
3. High genetic variation leads to more opportunities for the presence of beneficial alleles or traits. If the environment suddenly changes, and beneficial traits are already present in the population, then selection can increase the frequency of those traits and the population can rapidly evolve. However, high genetic variation does not guarantee that appropriate beneficial alleles will already be present in the population.

RECAP 20.6

1. Insects may be physiologically constrained by their system of respiration, which may not be able to support as large a body as that of birds. This is an example of an historical constraint that limits insect body size.
2. Anything that resulted in sudden, widespread environmental change would be likely to affect many species simultaneously. Examples include a meteorite or comet impact, widespread volcanic activity, or sudden climatic changes.

WORK WITH THE DATA, P. 431

- 1. Four groups of moths show clear indications of long wing tails, and each of these groups is closely related to moths that lack wing tails. Therefore the trait must have evolved in parallel at least four times. The long wing tails are present in 11 species on the tree, but some of these species are closely related to one another, and so the trait could have evolved in the common ancestor of each closely related species cluster. Therefore the trait appears to have originated about four times independently.
- 2. Although the long wing tails appear to have evolved four times independently, there is evidence that directional selection continued in many species as the trait evolved. For example, notice the parallel changes from green to yellow to red (indicating increasing length of wing tails) in many of the species.

WORK WITH THE DATA, P. 441

- 1. For *C. philodice*, 43.2% of all viable males are heterozygous, so 56.8% must be homozygous. To get expected numbers of heterozygous and homozygous mating males, we multiple the expected proportions (from all viable males) by the total number of mating males sampled. Therefore we expect to see (0.432)(50) = 21.6 heterozygous mating males, and (0.568)(50) = 28.4 homozygous mating males. If we repeat the same calculations for *C. eurytheme*, we expect (under the given assumption) to see (0.478)(59) = 28.2 heterozygous mating males and (0.522)(59) = 30.8 homozygous mating males.
- 2. Chi-square calculations for *C. philodice*:

Genotype	Expected (E)	Observed (O)	O - E	(O - E) ²	(O - E) ² /E
Heterozygotes	21.6	31	9.4	88.36	4.091
Homozygotes	28.4	19	-9.4	88.36	3.111

The sum of the last column gives the chi-square test statistic: 7.202. Since this value is greater than the critical value ($P = 0.05$) of 3.841, the observed results are significantly different from the expectations at $P < 0.05$. In other words, we can reject the null hypothesis and conclude that the proportions of each genotype (heterozygotes and homozygotes) of mating males are significantly different from the proportions of these genotypes seen among all viable males in *C. philodice*.

Chi-square calculations for *C. eurytheme*:

Genotype	Expected (E)	Observed (O)	O - E	(O - E) ²	(O - E) ² /E
Heterozygotes	28.2	45	16.8	282.17	10.005
Homozygotes	30.8	14	-16.8	282.17	9.162

The sum of the last column gives the chi-square test statistic: 19.167. Since this value is greater than the critical value ($P = 0.05$) of 3.841, the observed results are significantly different from the expectations at $P < 0.05$. In other words, we can reject the null hypothesis and conclude that the proportions of each genotype (heterozygotes and homozygotes) of mating males are significantly different from the proportions of these genotypes seen among all viable males in *C. eurytheme*.

- 3. (0.75)¹⁶ is approximately 0.01002. Therefore the investigators would need to analyze at least 16 larvae from each batch of eggs to judge the genotype of the father with 99 percent certainty. An easy way to find this answer is to multiply 0.75 × 0.75, and then multiply the answer by 0.75, and continue until the result is approximately 0.01. Keep track of the number of times you multiply by 0.75 to find the appropriate sample size.

FIGURE QUESTIONS

Figure 20.6 Over time, sexual reproduction led to new combinations of the existing genes. Many different genes affect bristle number, so the selection for high (and low) bristle numbers led to selection for new genetic combinations that produced high (or low) bristle numbers. In addition, there was selection for any new mutations at any genes that led to high (or low) bristle numbers.

Figure 20.12 If the mean value of a trait in a population is below the optimal value for that trait, then the mean will evolve to be closer to the optimum through directional selection. But, as the population mean reaches the optimum, then the population will experience stabilizing selection (with selection against individuals that are both below and above the population mean).

Figure 20.20 Although TTX resistance is an advantage within the range of the toxic newt, the alleles that confer TTX resistance also lead to slower movement by the snakes (a disadvantage). There is therefore a trade-off in the benefits versus the cost of TTX resistance. In the range of the newt, the advantage outweighs the cost; outside the range of the newt, the cost outweighs the benefit. Thus there is selection for TTX resistance where the snakes occur with the newt, but selection against TTX resistance elsewhere.

APPLY WHAT YOU'VE LEARNED

- 1. A *carolinensis* from islands with introduced *A. sagrei* have significantly larger to-e pads with more lamellae

compared to lizards from islands without *A. sagrei*. As the *A. sagrei* were only introduced to the islands in 1995, these differences in foot structure appear to have arisen since that time. The fact that the toepads have evolved so quickly indicates that there is strong selection for larger toepads with more lamellae in lizard populations on the invaded islands.

2. The common garden experiment confirms that the observed differences have a genetic basis, and are not due to different expression of the same genes on the two sets of islands. If the lizards raised in the common garden experiment had not shown the same level of differences that were observed in the wild populations, then the observed changes could not be attributed to evolution, which refers to genetic changes in populations over time.
3. The most important evolutionary process in this example is selection. Given that tree-top *Anolis* typically have larger toepads compared to ground-dwelling species, it is logical that lizards with larger toepads and more lamellae are more likely to survive and reproduce in tree tops (compared to lizards with smaller toepads and fewer lamellae). By living longer, lizards with larger toepads will produce more offspring over time, and so their genes will be increasingly represented in subsequent generations.
4. In this case, individuals of *A. carolinensis* with smaller toepads and fewer lamellae would have an advantage on the ground and on low perches on the invaded islands. Therefore, we would predict that the evolutionary change would occur in the opposite direction; the average toepads would become smaller on the invaded islands compared to un-invaded islands.
 - Selection for larger toepads appears to be occurring.
 - Mutation is certainly occurring in the populations (as it does in all species), although it likely has a very small effect at this time scale.
 - The populations on each island are likely to be fairly small, so drift is occurring.
 - Gene flow among populations is unknown, but it is likely to be low, since new invasions of islands appear to be rare.
 - Non-random mating among the lizards may be occurring, although there is no evidence of this process described in the experiment.
5. The other four processes of evolution (mutation, drift, gene flow, and nonrandom mating) are likely occurring as well, although they are less important to this example:
 - The variation in toepad size and number of lamellae would not exist without mutations in the genes that produce these structures, so mutation was critical for introducing genetic variation into the populations. But mutations occur very slowly, so very few new mutations that affect toepad size would be expected over 15 years.
 - Genetic drift is certainly occurring on the islands, because the populations on each island are limited. However, drift would not produce a consistent directional effect in toepad size across islands, and so it cannot account for the consistently larger toepads in *A. carolinensis* on invaded islands.
 - There was no attempt to measure gene flow among the islands in this experiment. But the fact that *A. sagrei* only occurred on islands where it was introduced suggests that inter-island movement of lizards is low and not likely a major factor in the study.
 - Lizards might choose mates based on their toepad size (non-random mating), which would affect the distribution of toepad size in the population, producing more variation on which selection could then act. However, there is no evidence for this process in the described experiment.

Chapter 21

RECAP 21.1

1. Phylogenetic trees can represent any process in which biological lineages diverge, such as speciation (in which case the tree will depict the evolutionary relationships among species), viral replication (in which case the tree will depict the evolutionary relationships among different viral lineages), or gene duplication (in which case the tree will depict the evolutionary relationships among genes). In most cases in this book, phylogenetic trees are used to depict the evolutionary relationships among species or higher groups of organisms.
2. Because homologous characters are similar as a result of their common descent. Similarities that result from convergent evolution (the wings of birds and insects, for example) can be misleading about evolutionary relationships if they are mistaken as homologous characters.
3. Selection for similar environmental conditions often leads to convergence in traits. For example, fish and dolphins both have fins and are similar in body shape because there is strong selection for these traits in an aquatic environment. But these traits have evolved independently in the two groups. Biologists can usually detect such homoplasies because they conflict with a large number of homologous traits in the groups that are similar as a result of their recent shared ancestry. Biologists can minimize homoplasies using the principle of parsimony.

RECAP 21.2

1. The pine tree and the sunflower.

2. The fern.
3. True roots and vascular cells.
4. No, because each trait can be placed along a single branch in the tree.

RECAP 21.3

1. The West Nile Virus in the United States appears to be most closely related to a strain of the virus isolated in Israel. A reasonable hypothesis is that the virus emerged in Africa in the 1930s and subsequently moved into Asia and Europe, probably multiple times. In the late 1990s, a strain of the virus from Israel appears to have been transported to New York, perhaps carried by mosquitoes on an airplane or in a cargo shipment. Once in the United States, the virus spread quickly in native bird populations across North America.
2. The rate of divergence is represented by the slope of the regression line. Since the regression line goes approximately through the origin (0, 0), the slope is approximately 7.5% change in *cyt b* per 4 my, or 1.875% change per million years.

RECAP 21.4

1. Classifications One and Three (the group Reptilia is paraphyletic if the birds are excluded).
2. Classification Three (the group Homotheria is polyphyletic).
3. Classification Two.

WORK WITH THE DATA, P. 457

Ancestor of A, C, D, and E: CCGGGCCCCCCCCAACCGGTACAA
Ancestor of B, F, G, and H: CCGGGCCCCCCCCGACTGGCGCGG
Ancestor of A, B, C, D, E, F, G, and H: CCGGGCCCCCCCCGACCGGCACGG

3. The reconstructed phylogeny requires 23 transitions and only 1 transversion. The viruses were grown in the presence of a mutagen, and the mutagen used in this experiment results predominantly in transitions.

FIGURE QUESTIONS

Figure 21.8 If the HIV sequences from the victim had been found to be more closely related to those of any other HIV-positive individuals in the local community than they were to those of the physician's patient, then the phylogeny would be inconsistent with the alleged crime, and the results could have been used to exonerate the physician.

Figure 21.12 The expected branch length would be about 0.09 substitutions per nucleotide.

APPLY WHAT YOU'VE LEARNED

1. The individual labeled CC01 is consistent with being the source of the infection, because that is the only individual with HIV sequences that are more closely related to HIV sequences in all of the other individuals, rather than to sequences sampled only within a single individual. Viruses from CC01 are found across the tree, which is consistent with CC01 transmitting viruses over time to the other individuals. (In the trial, CC01 was revealed to be the defendant in the case).
2. The viral sequences sampled from each of the other individuals in the cluster are monophyletic, indicating a single origin, with no further transmission to other individuals. Thus, the tree is inconsistent with CC02–CC08 being the original source of infection in this cluster.
3. The outgroup was needed to root the tree, which in this case identifies the direction of the transmission of events. Inclusion of viruses from outside the epidemiological cluster also tests the hypothesis that all viral sequences in this cluster are derived from a single ancestral virus.

Chapter 22

RECAP 22.1

1. Biologists are interested in many aspects of species, and their emphases differ depending on the questions they are asking about species. Biologists who are interested in the processes that led to lineage-splitting emphasize the mechanisms that allow lineages to diverge and to remain isolated from one another after divergence (i.e., how species come into existence and remain distinct from one another). Biologists who are mostly concerned with identifying species and understanding their distribution in time and space are more likely to emphasize historical aspects and how we can tell species apart (i.e., how we recognize species in nature). Still other biologists may be interested primarily in how species co-exist in communities, and these biologists are likely to emphasize the ecological role of species (how do species differ in their adaptations and niches?). Each of these emphases leads different biologists to emphasize different attributes of species.
2. Sexual lineages must have a substantial degree of reproductive isolation or they cannot remain distinct from one another. So even if a biologist is primarily using a morphological species concept, the morphological differences between species cannot be maintained in time and space unless the two species are largely reproductively isolated from each other. Obviously, reproductive isolation is central to the biological species concept. The many versions of lineage species concepts conceptualize species as distinct lineages in the tree of life. If these lineages are to remain distinct from one another through time, they must be substantially reproductively isolated from one another. Thus, reproductive isolation is important (either directly or indirectly) to all of the various species concepts.
3. The biological species concept limits its scope to “actually or potentially interbreeding natural populations.” Clearly, asexual organisms do not form such populations. Nonetheless, they do form lineages that exist in time and space, and these lineages may be maintained by other factors, such as available niche space. Most biologists who emphasize the biological species concept are interested primarily in the mechanisms that lead to reproductive isolation and its maintenance over time. The lineage concepts of species are not in conflict with the biological species concept, but they represent a more inclusive way to think about all species, regardless of their sexuality. The lineage concepts also allow biologists to study species across geological time (where reproductive interactions are not possible).

RECAP 22.2

1. If the only difference between the diverging lineages is at a single locus, then both of the new alleles must

be functional when they interact with the products of other gene loci (in both lineages). Any genetic incompatibility produced by these new alleles would be expected to affect the parental lineages as well. There are much greater numbers of possible incompatibilities across different gene loci. Rather than two deleterious changes at the same locus (one in each lineage), the Dobzhansky-Muller model allows neutral changes at any pair of loci whose products interact. It is the negative interaction of these products in the hybrid between the two lineages that results in genetic incompatibility.

2. Segregation doesn't occur normally, because chromosome arms are linked differently on the different species, resulting in duplications and deletions in meiosis. If two different fusions of chromosomes occur in two different lineages, then the resulting chromosomes cannot pair normally in meiosis in the hybrids. If you attempt to diagram meiosis in the hybrid that would result from a cross of the divergent lineages in [Figure 22.4](#) (see below), you will see that homologous pairings require parts of different chromosomes to align with one another. These chromosomes will then be pulled in two different directions as the cell divides in meiosis I, resulting either in a likely failure of the cell to divide or in an uneven distribution of the chromosome arms in the two daughter cells. Production of normal cells with an even distribution of the various chromosomes' arms is impossible, so the hybrid organisms will not produce functional gametes.

3. A likely possibility is that the incompatible alleles have not yet become fixed in the various strains, so only some combinations of crosses result in genetic incompatibility.

RECAP 22.3

1. Polyploids (e.g., tetraploids) can be produced in the first generation. Hybrids between diploids and tetraploids may be produced in the second generation, forming triploid individuals, but meiosis in the triploids results in gametes with unbalanced chromosome numbers, which results in sterile offspring. An F1 tetraploid is able to self-fertilize or mate with another tetraploid and produce fertile offspring. Thus, the polyploidy organism is reproductively isolated from the diploid species, making it a different species.
2. Species that arise in allopatry initially occur in separate, but usually adjacent, ranges (e.g., see [Figure 22.6](#)). Therefore, we would expect many closely related species to exhibit this same pattern. The ranges of highly mobile species are more likely to change over time, so the pattern should be strongest among relatively sedentary species. Biologists have confirmed these predictions across many diverse groups of organisms.
3. a.

- b. Yes, because the curve for the number of species lags behind the curve for the number of islands; but the two curves exhibit very similar changes in slope through time. As new islands arise, new opportunities for speciation also arise. The number of species at any one time is always just below the number of distinct islands.
- c. There are currently 18 islands in the archipelago and only 14 species (as recognized by some biologists). This suggests that there are still opportunities for additional speciation by geographic isolation. Based on our graph from question 3a, we expect populations of species that occur on two or more islands to diverge into distinct species over time. To test this hypothesis, we could collect samples of each population and examine genetic divergence between the samples. Significant genetic divergence between the populations on different islands suggests that the distance between the islands is a significant barrier to gene flow, so the populations are expected to diverge into distinct species over time (see [Key Concept 22.2](#)). Indeed, as we noted in the text discussing Darwin's finches, some biologists recognize the genetically divergent (but morphologically similar) species on different islands as distinct species, which is why they recognize as many as 18 different species of Darwin's finches.)

RECAP 22.4

1 a.

- d. Hybrids represent a smaller proportion of the samples at each successive life stage, indicating lower hybrid survivorship compared to either parental type. Postzygotic isolating mechanisms that are consistent with this pattern include low hybrid zygote viability and (for the adult frogs) low hybrid adult viability.
- e. Selection against hybridization would favor non-overlapping breeding seasons between the two species. Over time, more individuals that result from offset breeding seasons would be expected to survive (since no hybrids are produced in these cases). Assuming there is a genetic component that influences when a frog will breed, the populations would be expected to shift to produce non-overlapping breeding seasons (as seen in allopatric versus sympatric populations of these two species; see [Figure 22.11](#)). As overlap between breeding seasons is reduced, we would expect to see fewer hybrids at every life stage.
2. There are many possible designs of experiments that might prove informative. Here is an example of one that would examine the effect of flower position on pollinator attraction: Take one species of flower and divide the flowers into two groups. Position each flower to be either upright or pendant, then record the number and type of pollinators that are attracted to flowers in each group. Test to see if the differences between the two groups are statistically significant.
3. There is gene flow into the hybrid zone, but the hybrid zone acts as a "genetic sink." The hybrids are less fit compared to either parental type, so there is little gene flow out of the hybrid zone. An expanding hybrid zone would require hybrids to move out of the hybrid zone and compete successfully against individuals of each of the two parental species.

RECAP 22.5

1. If a pollinator specializes on one particular flower type, that will reduce opportunities for cross-fertilization among different flower types. Any polymorphism in flowers can thus lead to rapid genetic divergence between individuals that express each flower type. A similar process occurs with sexual selection in animals. If some females prefer to mate with males that have a certain trait and other females prefer a different male trait, then the population can quickly lead to genetic isolation and differentiation in the two groups.
2. A new immigrant to an isolated area may encounter no competition for a particular feeding strategy or life style. Under these conditions, there are many “open niches” that can be co-opted by the invading species, leading to a rapid increase in speciation.

WORK WITH THE DATA, P 479

1. For red flowers, the proportion of seeds from hybrid matings is 0.1298 (27/208). The 95% confidence limits of this proportion are approximately 0.09-0.18. For pink flowers, the proportion of seeds from hybrid matings is 0.3813 (53/139). The 95% confidence limits of this proportion are approximately 0.30-0.47.
2. The null hypothesis is that there is no significant difference in the proportion of hybrid seeds produced from red versus pink flowers. This hypothesis is rejected; the probability that the null hypothesis is true is $P < 0.0002$.
3. Scientific studies often raise new questions that can be addressed by follow-up experiments. Repeating this study in several different sites of sympatry and allopatry would address the unlikely possibility that red flowers are favored at the study site because of local conditions that have nothing to do with the presence of *P. cuspidata* (such as the local abundance of pollinators that prefer red flowers). A possible control experiment would involve removing all *P. cuspidata* from an area of sympatry and testing to see if the absence of *P. cuspidata* eliminates the selective advantage of red-flowered *P. drummondii*.

FIGURE QUESTIONS

Figure 22.5 Genetically distant pairs of species almost always develop Dobzhansky-Muller incompatibilities, because there are many more divergent genes that are likely to function poorly together. But Dobzhansky-Muller incompatibilities can develop with divergence at just two genes, so some otherwise genetically similar pairs of species can become reproductively isolated very quickly.

Figure 22.6 The glaciers eliminated most of the highlands that formerly connected the two areas, so there is now little appropriate habitat that would allow the differentiated species to interact. But if the interactions were possible, it is likely that the hybrids would exhibit reduced fitness (as explained by the Dobzhansky-Muller model), and there would be selection for prezygotic isolating mechanisms that would minimize hybridization.

Figure 22.11 Overlap in breeding seasons in areas of sympatry results in increased hybridization. The hybrids have reduced fitness, so there is selection in favor of frogs that breed at times when hybridization is less likely.

APPLY WHAT YOU'VE LEARNED

1. Hydrocarbon 2 shows a pattern consistent with reinforcement. Under reinforcement, the difference between the sympatric populations and the other species should be greater than the difference between the allopatric populations and the other species. This pattern is observed only for hydrocarbon 2.
2. Hydrocarbon 2 in the allopatric populations of *D. serrata* would be expected to evolve to be more like the sympatric populations and less like *D. birchii*. Thus, its concentration would be expected to decrease in the lab populations. The concentrations of the other hydrocarbons would be expected to remain about the same, as they do not appear to be undergoing reinforcement.
3. The frequency of hybridization should decrease. The artificial selection is operating on the hydrocarbon because hybridization with the other species is disfavored. As a result, fewer hybridizations should take place.
4. The level of postzygotic reproductive isolation should not change, as postzygotic isolation generally does not evolve via direct selection.

Chapter 23

 Sequence *b* ATT—CAGGGTATA—CC
 Sequence *c* ATTGCAGCGTATAACC
 Sequence *d* ATTGCAGGGTATA—CG

2. A simple count of nucleotide differences misses multiple substitutions, including coincident substitutions, parallel substitutions, and back substitutions (see [Figure 23.2](#)). Evolutionary models can be used to estimate the number of multiple substitutions that have occurred, based on the number of actual differences that are observed. For example, the second nucleotide of Sequences *a* and *b* from Question 1 exhibits a single difference between an A and T. Although a single substitution from a T to an A in Sequence *a* could explain this difference, it is also possible that there were two substitutions (e.g., first a substitution from T to C, then another from C to A). A simple count of differences misses such multiple substitutions.

RECAP 23.2

1. This problem can be investigated by sequencing and comparing the genes for opsins in surface-dwelling (eyed) and cave-dwelling (eyeless) crayfish. If the genes of the eyeless species are no longer under any selection, we would expect to observe a similar rate of synonymous and nonsynonymous substitutions in the genes. If there has been strong selection for a new function (something other than vision), we would expect a higher rate of nonsynonymous substitutions compared with synonymous substitutions (indicating positive selection). We would compare the rates observed in the eyeless species to the rates seen in the surface-dwelling (eyed) species. In the surface-dwelling species, we would expect to see a higher rate of synonymous compared with nonsynonymous substitutions, which is expected under purifying selection.

2. A given neutral mutation will arise more often in a large population than in a small population, but any mutation that does arise is more likely to be fixed in a small population than in a large population. These two influences of population size exactly cancel each other out, so that overall, the rate of fixation of neutral mutations depends only on the mutation rate and is independent of population size. In a diploid population of size N and a neutral mutation rate μ per gamete per generation at a locus, the number of new mutations would be, on average, $2N\mu$, because $2N$ gene copies are available to mutate. The probability that a given mutation will be fixed by drift alone is its frequency, which equals $1/(2N)$ for a newly arisen mutation. We can multiply these two terms to get the rate of fixation of neutral mutations (m) in a given population of N diploid individuals:

$$m = 2N\mu \quad m = 2N\mu \frac{1}{2N}$$

But we can simplify this equation by canceling out $2N$ on the right side of the equation:

$$m = \cancel{2} \cancel{N} \mu \frac{1}{\cancel{2} \cancel{N}}$$

$$m = 2N\mu \frac{1}{2N}$$

This just leaves $m = \mu$. In words, the rate of fixation of neutral alleles is equal to the mutation rate of neutral alleles and independent of population size.

- 3a. Codon numbers 12, 15, and 61 are likely to be evolving under positive selection for change because each of these codons has experienced a higher rate of nonsynonymous substitutions (which give rise to amino acid replacements) than synonymous substitutions.
- b. Codon numbers 80, 137, 156, and 226 are likely evolving under purifying selection, as the vast majority of changes at these codons are synonymous substitutions, which do not result in amino acid replacements. Substitutions that result in amino acid changes (nonsynonymous substitutions) undoubtedly occur but are usually selected against in the population. Codon number 165 has experienced similar numbers of synonymous and nonsynonymous substitutions. There are approximately three times as many possible nonsynonymous substitutions as there are synonymous substitutions. Therefore the number of synonymous substitutions is slightly higher than expected if the rates of each type of substitution are equal. Codon 165 may be evolving under weak purifying selection; it is the codon that is closest to neutral among the codons shown in the table.
4. Example hypothesis 1: Genome size varies primarily because noncoding DNA can effect changes in gene expression, and many species have evolved largely through changes in gene expression.
Example hypothesis 2: Genome size varies primarily as a function of population size. Species with small population sizes may accumulate large amounts of noncoding DNA because of weak selection against accumulation of slightly deleterious "junk" DNA in small populations.
Contrasting the two hypotheses: If hypothesis 1 explains most of the variation in genome size among organisms, then we would expect genome size to be largely independent of population size, which is not the case. For example, [Figure 23.9](#) indicates that the species with the largest genomes, like the lungfish, generally have much smaller population sizes than the species with the smallest genomes, like the *E. coli* or yeast. However, both hypotheses may explain some of the variation in genome size, and careful, controlled experiments would be needed to determine how much of the variation in genome size is explained by the effects of selection (hypothesis 1) versus population size (hypothesis 2).

RECAP 23.3

1. New genes can add new functions. For example, lateral transfer of a gene that confers antibiotic resistance would provide a huge advantage to bacteria that are subjected to antibiotics.
2. The tree indicates that three gene duplication events and one gene loss occurred. In the tree below, the three gene duplication events are marked in blue, and the gene loss is marked in red. Gene duplication event 1 marked the duplication between gene C and the ancestor of genes A and B. Gene duplication event 2 resulted in genes A and B. Gene duplication event 3 happened in the ancestor of humans and resulted in human genes C1 and C2. Finally, there was a loss of gene B in gorillas (event 4 on the tree).

3. Gene duplication provides the raw material for much of evolution. A duplicated gene is free to diverge from its ancestral function, since the original copy of the gene can continue to provide the original function.
4. Concerted evolution refers to highly repeated gene families where all the copies evolve together so that all the copies maintain a high degree of similarity. Two processes can produce concerted evolution: unequal crossing over and biased gene conversion. The two processes differ as follows:

(A) Unequal Crossing over DNA

(B) Biased gene conversion

RECAP 23.4

1. Comparisons of evolutionary changes in proteins, made across species in which these proteins differ in function, provide insight into how change in protein sequence relates to change in protein function. For example, changes across many different genes in many different species of puffer fish show which changes are related to the evolution of tetrodotoxin resistance in sodium channel genes. These studies help us understand the function of sodium channels, which helps us understand the genetic basis of various neurological pathologies.
2. Starting with a large pool of random sequences, in vitro evolution involves rounds of selection and mutation to produce new molecules with specific functions. This corresponds exactly to the processes of mutation and natural selection in natural populations. The only difference is that the selection and mutational processes are controlled by humans in a laboratory setting, to produce a molecule with a desired function.
3. Most emerging diseases are caused by living, evolving organisms. Evolutionary comparisons of DNA sequences from these pathogens allow quick identification and often reveal the source of the disease (from a particular host species or geographical area). Previously unidentified pathogens can be compared with their closest relatives. This often allows biologists to make predictions about the best

strategies for controlling the spread of the disease.

WORK WITH THE DATA, [P. 494](#)

1.

Positions 14, 21, 50, 75, and 87 show convergence in amino acids between cattle and langur.

2. Position 17 is convergent between cattle and the ancestor of langurs and baboons.
3. No, there are no other convergent changes. The fact that almost all convergent events occur between cattle and langurs supports the hypothesis that these convergent changes are related to the convergence in function associated with a shift to foregut fermentation.

WORK WITH THE DATA, [P. 503](#)

1. Birds appear to be the original source of influenza viruses that now cause flu in the various mammal species (horses, pigs, and humans). The bird lineages extend to the base of the tree, and appear to be closely related to each lineage of influenza virus that occurs in a mammal.
2. The tree shows five cross-species transmissions: two from birds to horses, two from birds to pigs, and one from birds to humans. The human flu viruses are most closely related to viruses in pigs (hence the common name "swine flu"), and it is possible that the virus was transferred from birds to pigs and then from pigs to humans in a short period of time late in the second decade of the 1900s.
3. In 1918, a new strain of influenza had just entered human populations (as well as pig populations). Humans' immune systems would not have had any prior experience with this new strain of influenza, and so would not have been prepared for an effective defense.
4. Earlier flu cases were likely caused by other cross-species transfers of different strains of influenza into human populations. Those flu strains appear to have been eliminated from human populations, and so were not available for sampling in this study (and therefore do not appear on the tree).

FIGURE QUESTIONS

[Figure 23.10](#) Approximately 100 million years ago.

[Figure 23.12](#) Two gene duplication events were restricted to the zebrafish lineage: the event that gave rise to the zebrafish *En1a* and *En1b* genes, and the event that gave rise to the zebrafish *En2a* and *En2b* genes.

APPLY WHAT YOU'VE LEARNED

1.

There are, on average, 54 synonymous substitutions between lineages that diverged 18 million years ago (36 million years of evolution altogether). Thus, there have been about 1.5 synonymous substitutions per million years for the entire exon. Given five generations per year and 600 synonymous sites, the rate is 3×10^{-7} synonymous substitutions per generation for the entire exon and 5×10^{-10} synonymous substitutions per site.

2. The per-site synonymous substitution rate is 5×10^{-10} (from Answer 1 above). If all synonymous substitutions are neutral, the substitution rate should equal the mutation rate.
3. Based on 3×10^{-7} synonymous substitutions per generation for the entire exon, 270 synonymous substitutions are expected ($90,000,000 \text{ years} \times 2 \text{ lineages} \times 5 \text{ generations/year} \times 0.0000003 \text{ synonymous substitutions/generation}$). This is much higher than the 174 observed synonymous differences between these two species. A likely explanation for the discrepancy is that not all of the actual substitutions are observed, because of multiple, coincident, parallel, and back substitutions.
4. There are, on average, 18 nonsynonymous substitutions between *D. ananassae* and the other three species. Given 36 million years of evolution, 2000 nonsynonymous sites, and five generations per year, the per-generation, per-site nonsynonymous substitution rate is 5×10^{-11} . This is one-tenth the synonymous rate of 5×10^{-10} calculated in Question 1. This much-lower nonsynonymous rate suggests strong purifying selection.
5. The biologist is probably incorrect, and the gene is likely to still be a functional gene and not a pseudogene. Because they have lost function, pseudogenes are unlikely to be affected by selection. Thus, nonsynonymous sites of pseudogenes should have substitution rates about the same as those of synonymous sites, which is not what is observed.

Chapter 24

RECAP 24.1

1.

2.

3. Site z falls near the predicted border between the Ordovician and Silurian periods on the map shown in the answer to Question 2. Therefore it would be the best site to examine to refine the border between these two periods.

RECAP 24.2

1. Climate refers to long-term average expectations of weather at a given location; weather refers to the daily events. Even if the long-term expectations of climate are of gradual warming, we still expect occasional winter blizzards at a given location away from the tropics. A long-term increase in the average temperature of 1°C represents a major climate change, but we would still expect a wide range of temperature conditions throughout the year at a given location.
2. Several major environmental changes occurred near the end of the Precambrian. This was the end of the “snowball Earth” period, when life was likely confined to a few relatively warm areas, such as hot springs and thermal vents. Warming of Earth resulted in rapid diversification of life. There was also a rapid accumulation of oxygen in the atmosphere. Multicellular organisms have higher metabolic requirements than do single-celled organisms. As O_2 accumulated in Earth’s atmosphere from the earliest photosynthetic organisms, it was initially toxic to the single-celled, anaerobic organisms that existed on early Earth. Some species evolved to tolerate and then use O_2 for aerobic respiration, which allowed the evolution of large colonies of organisms. Eventually, cooperation among the different individuals in the multicellular colonies led to the evolution of integrated, multicellular organisms.

RECAP 24.3

1. A major factor was the evolution of two genes in legumes that allowed these plants to use atmospheric nitrogen directly by forming symbioses with a few species of nitrogen-fixing bacteria. This change dramatically increased the amount of nitrogen available for terrestrial plant growth.
2. The Archean and Proterozoic eons lasted about 1.3 billion and 2.0 billion years, respectively, compared with the 0.542 billion years of the Phanerozoic eon. Yet most of the tree depicts events in the much shorter Phanerozoic eon, since most of the major groups of life shown on the tree diverged during this time. If the tree depicted time proportionally, the branches at the base of the tree would need to be much longer. However, if this change were made, the divergence of the eukaryotes would be so compressed that their relationships could not be shown clearly on one page.

WORK WITH THE DATA, P. 516

1. Since $W = S(1 + R)^N$, then $W = (1 \text{ g})(1.0001)^{50,000} = 148.38 \text{ grams}$.
2. The Permian lasted 48 million years (299 mya to 251.0 mya); therefore 50,000 years represents about one-thousandth of this time, or 0.1 percent.
3. Given that even a very modest increase in body size of 0.01 percent per generation is enough to result in an increase in body mass from 1 gram to more than 148 grams in just 50,000 years; that 50,000 years represents only about one-thousandth of the Permian; and that the experiment shows that increases in atmospheric oxygen can result in much more rapid evolution of insect body size than calculated above, it seems reasonable to conclude that the increased oxygen concentrations during the Permian were sufficient to account for the evolution of giant dragonflies.

WORK WITH THE DATA P. 517

1. First, plot the data from the table:

Then approximate an extinction curve from the plotted points:

- The survivorship after 2 years would clearly be lower than after 1 year. After 1 year, about half the populations of size 20 would go extinct. To calculate the number that would go extinct after 2 years, you would need to know the distribution of population sizes among the half of the populations that did not go extinct in the first year. If we assume that the average size of the surviving populations was still 20 after 1 year, then we would expect another half of the remaining populations to go extinct in the second year (for a 2-year extinction rate of 75 percent of the original populations).

FIGURE QUESTIONS

Figure 24.3 There is a spreading zone in the middle of the Pacific Ocean where new lithospheric crust is forming. This pushes the oceanic plates on either side to the east and west, forming subduction zones where oceanic plates meet continental plates on both sides of the Pacific Ocean.

Figure 24.4 When Earth cools, more of its water is tied up in ice on land, in the form of glaciers. Thus there is less water in the oceans, so sea levels are lower.

Figure 24.8 Ash and gases produced by massive volcanic eruptions near the end of the Permian blocked sunlight and resulted in rapid cooling of Earth. There was massive die-off of the lush Permian forests, and the decay of these forests used up much of the atmospheric oxygen. In addition, the loss of these photosynthetic organisms meant that less oxygen was being produced to enter the atmosphere.

APPLY WHAT YOU'VE LEARNED

- The Ediacaran fossils would have been discovered in older sedimentary strata lying below younger strata where Cambrian-type shelly biota fossils were found. There may have been some overlap where both fossil types were found. The time line provides evidence for this answer, since it indicates that Ediacaran fossils are older than Cambrian-type shelly biota and that there was a short period during which both were present simultaneously.

2. The Ediacaran fauna evolved only after levels of atmospheric oxygen were high enough to support multicellular life forms. Therefore one factor that favored the success of the Ediacaran was the increase in atmospheric oxygen that occurred at this time. Another factor was the ending of glaciation events, which occurred as Earth warmed. The resulting loss of ice cover allowed sunlight to penetrate seawater more effectively, which spurred increased rates of photosynthesis. This further increased oxygen concentrations in aquatic environments. Warmer temperatures in general increased reaction rates, including those in life forms to speed their growth and reproduction; this also favored success of the Ediacaran fauna at that time in Earth's history.
3. The physical environment remained favorable for the evolution of multicellular organisms, since the Cambrian-type shelly biota also arose during this time period. Therefore it was not the physical environment that led to the extinction of the Ediacaran fauna. Most likely, the Ediacaran animals were preyed on by other organisms. They would have been easy prey since they were sessile and large and lacked protective exoskeletons. The Cambrian-type shelly biota were better protected. Their exoskeletons and motility made them much less vulnerable to predation, and thus to extinction.
4. The statement suggests that the lack of fossil discovery does not mean that organisms producing those fossils did not exist. The lack of discovery of fossils may just mean that fossils exist but have not yet been found, or that the organisms died without leaving fossils, or that fossils were formed but have degraded over time. We have to keep open the possibility that the Ediacaran biota lived before or beyond the time period for which we have fossil evidence at present. However, until such evidence is found, the available evidence supports the hypothesis that the Ediacaran fauna arose and went extinct in the time period shown in the diagram.
5. Suppose a geological formation is dug up and surveyed for the presence of fossils. If Ediacaran fossils are found in the same strata as fossils of organism X, one could conclude that organism X existed in the same time period as the Ediacaran biota.
This would date the existence of organism X to the same time period as the Ediacaran biota. This would be possible because fossils located in the same strata were deposited in sediment at the same time. The dating of the strata would be possible because the Ediacaran biota existed in a fairly narrow time window. This would all change, however, if new evidence placed Ediacaran biota at an earlier or later time than what scientists have observed so far.

Chapter 25

RECAP 25.1

1. Before DNA sequencing was developed, biologists usually grouped all prokaryotes together, emphasizing the differences between eukaryotes and prokaryotes. But the characteristics that differentiated these two "groups" (such as the presence of a nucleus, or the various organelles) are all derived features of eukaryotes. When gene sequences were compared across all of life (especially the ribosomal RNA genes, which are easily compared across all living organisms), it became clear that the diversity among "prokaryotes" was far greater than the diversity among eukaryotes. Indeed, it soon became apparent that the ribosomal RNA genes of prokaryotic archaea were actually more similar to the ribosomal genes of eukaryotes than they were to the ribosomal RNA genes of bacteria, and Archaea was proposed as a domain separate from Bacteria. As biologists studied Archaea in more detail, they discovered that many other features were also distinct from Bacteria.

2.

Expected tree based on gene X:

Expected tree based on consensus of non-transferred genes:

3. The genomes of eukaryotes contain mostly genes that are more closely related to prokaryotic archaea than to bacteria. This leads biologists to conclude that an ancestral prokaryotic archaean lineage first acquired the features that are characteristic of eukaryotes (such as the nucleus). These early eukaryotes then acquired an endosymbiotic proteobacterium, which was eventually incorporated as the eukaryote mitochondrion. Later, one group of eukaryotes acquired another endosymbiont, this time an early cyanobacterium, which became the chloroplast of photosynthetic eukaryotes.

RECAP 25.2

1. Similarities between any two groups shown in the table can occur for three reasons: (1) the similar feature between two groups is ancestral to life, and the third group has a derived character; (2) the similar feature is a derived character, indicative of a shared ancestry (such as between prokaryotic archaea and their eukaryotic relatives), and the third group (bacteria) has the ancestral condition; or (3) the two endosymbioses of bacteria within eukaryotes may have led to similarities between bacteria and eukaryotes. An example of the first category is that the two prokaryotic groups lack a nucleus, whereas eukaryotes have a nucleus (a derived character). The similarity of the RNA polymerases of prokaryotic archaea and eukaryotes is likely an example of the second category (a derived feature that indicates an evolutionary relationship between these two groups). A possible example of the third category is the ester-linked membrane lipids of bacteria and eukaryotes, since the prokaryotic archaea have ether-linked membrane lipids.
2. All organisms that are alive today are descendants of a common ancestor of life. Many changes have occurred in all these different species, including prokaryotes as well as eukaryotes. Many prokaryotes have undergone radical changes that allow them to live in extreme environments or in unusual ways. Numerous examples could be used, such as the following: One group of euryarchaeotes, the extreme halophiles (salt lovers), live exclusively in very salty environments, and some can live in lakes with pH

values as high as 11.5. They have many adaptations that allow them to live in these environments, and so they are more “derived” in this respect than is any eukaryote. As another example, several groups of bacteria, such as chlamydias, are highly derived intercellular parasites. They have many derived changes that allow them to have very small cells than can live within the cells of other species. Thus the terms “primitive” and “derived” make sense only with respect to a particular feature of the organism, and no living organisms can be considered to be primitive overall (i.e., the common ancestor of life was very different from all organisms that are alive today).

RECAP 25.3

1. Biofilms represent a complex community of microbial organisms, living together in a gel-like polysaccharide matrix. Many free-living prokaryotes that come into contact with a solid surface bind to the surface and secrete a sticky polysaccharide, which protects the cells. These cells may then secrete signal molecules that attract other microorganisms to the matrix, which develops into a complex community of organisms over time. This community may become highly resistant to attack and become very difficult to remove. Biofilms are of considerable interest to human health and industry, as they may form on any solid surface (e.g., teeth, contact lenses, artificial joints, the inside of pipes), resulting in decay. Biofilms were also critical to the evolution of many multicellular communities, such as stromatolites.
2. Bacteria are essential for healthy digestion, and only a very few types of bacteria are pathogens. Humans use some of the metabolic products, such as vitamins B12 and K, that are produced by bacteria that live in the large intestine. Large communities of bacteria also line human intestines with a dense biofilm, which aids nutrient transfer from the gut into the human body. Thus our gut microbiome is essential to human health.
3. Nitrogen-fixing prokaryotes convert nitrogen from the atmosphere into a chemical form that is usable by living organisms. In addition, denitrifying bacteria release organic nitrogen back into the atmosphere as nitrogen gas, keeping nitrogen from eventually leaching into the oceans. Thus these two groups of bacteria (nitrogen fixers and denitrifiers) allow the cycling of nitrogen and make life on land possible.

RECAP 25.4

1. The greatly reduced genomes of most viruses provide few sequences that can be compared with other organisms. Also, the genomes of many viruses evolve very quickly, making comparisons even more difficult. The reduced nature of viruses provides few morphological clues to their relationships, and their tiny size means they do not produce fossils. Viruses have evolved many times throughout the history of life, so they are related to organisms across the tree of life. For all of these reasons, it is often difficult to place viruses precisely on the tree of life.
2. Many viruses probably represent escaped components of cellular organisms that now evolve independently of their hosts. Other viruses are likely to represent highly reduced, parasitic organisms that evolved from cellular ancestors but lost their cellular structures as they became independent of their cellular hosts.
3. Viruses called bacteriophages, or “phages” for short, infect and kill bacterial cells. Phage therapy, first developed during World War I, involves applying these phages to kill pathogenic bacteria. Phage therapy was largely replaced by the use antibiotics in the 1930s and 1940s. With the increase in evolution of bacterial resistance to antibiotics, however, phage therapy is once again an active area of research.

WORK WITH THE DATA, [P. 538](#)

1.

2. 105°C, where growth is fastest (generation time is lowest).

3. Simply lower the temperature of these cell cultures to below 120°C and look for cell growth.

FIGURE QUESTIONS

Figure 25.4 Lateral gene transfers are most likely to occur when there is a selective advantage to the transfer. One species may receive genes from many others, but the chances are smaller that a substantial portion of the genome of one species will be transferred into another. In contrast, the stable core of genes controls critical metabolic functions of the cell, so all of these genes are expected to be inherited from ancestors to descendants together.

Figure 25.24 Parasitic bacteria can depend on the gene products of their hosts, so some of their genes can be lost without loss of function. Small genomes allow smaller cell size, and small size is beneficial for a parasite that lives within other cells.

APPLY WHAT YOU'VE LEARNED

1. As a denitrifier, *Paracoccus denitrificans* would be most appropriate to reduce nitrate concentrations. Its thermal range would also be appropriate under most environmental conditions.
2. As an obligate anaerobe, *Clostridium novyi* would be appropriate to use in hypoxic conditions. Its thermal range is also suitable for mammalian body temperatures.
3. *Trichodesmium thiebautii*. Because the addition of ammonium temporarily increased the productivity of the ecosystem, one can infer that the ecosystem is nitrogen-limited. As a nitrogen fixer, *T. thiebautii* converts atmospheric nitrogen into a form other organisms can use.
4. *Clostridium novyi*. Vancomycin targets bacteria with thick peptidoglycan-filled cell walls. That is the defining characteristic of Gram-positive bacteria, and *C. novyi* is the only Gram-positive bacterium in the table.

Chapter 26

RECAP 26.1

1. Loss of the stiff prokaryotic cell wall allowed infolding of the cell membrane, greatly increasing the surface area of the cell without increasing its volume. These infoldings also allowed for greater structure within the cell and eventually led to the evolution of the endoplasmic reticulum.
2. When atmospheric oxygen concentrations were low early in Earth's history, organisms could use only anaerobic respiration. Increased availability of atmospheric oxygen allowed the evolution of aerobic respiration, which proceeds more rapidly and harvests energy more efficiently than anaerobic respiration does. But as cells increased in size, they would decrease in surface area-to-volume ratio unless the cell

membrane had infoldings. Increased levels of atmospheric oxygen also led to the endosymbiosis of an aerobic bacterium (the ancestor of the eukaryotic mitochondrion), which facilitated the evolution of aerobic eukaryotes.

3. The three rRNA genes of corn are not one another's closest relatives because the nuclear, mitochondrial, and chloroplast genomes have different origins, and the relationships shown in the tree reconstruct the endosymbiotic events that gave rise to mitochondria and chloroplasts.
4. The mitochondrial genome of corn is more closely related to the genome of *E. coli* than it is to the nuclear genome of corn because the mitochondria were derived from an endosymbiosis with a proteobacterium. Likewise, the chloroplast genome of corn is more closely related to the genome of *Chlorobium* than it is to the nuclear genome of corn because the chloroplasts were derived from an endosymbiosis with a cyanobacterium.
5. The term "protists" is used, for convenience, to refer to a diverse group of distantly related, polyphyletic microbial eukaryotes. Some protists are more closely related to each of the major groups of multicellular eukaryotes (including plants, fungi, and animals) than they are to one another.

RECAP 26.2

- 1a. Foraminiferans have external shells of calcium carbonate, whereas radiolarians have long, stiff pseudopods and radial symmetry. The external shells of foraminiferans and the internal skeletons of radiolarians are both important components of ocean sediments and sedimentary rocks.
 - b. Ciliates are covered with numerous hairlike cilia, whereas dinoflagellates generally have two flagella (one in an equatorial groove and the other in a longitudinal groove). Both ciliates and dinoflagellates have sacs, called alveoli, just beneath their cell membranes, which identify them as alveolates.
 - c. Diatoms are unicellular and are typically composed of two nested plates (like a petri dish). In contrast, brown algae are large, multicellular organisms composed of branched elements or leaflike growths. Both diatoms and brown algae are photosynthetic.
 - d. The vegetative unit of a plasmodial slime mold is a plasmodium: a wall-less mass of cytoplasm containing numerous diploid nuclei. In contrast, the vegetative unit of cellular slime molds consists of separate, single amoeboid cells. In both groups, when environmental conditions become unfavorable, the vegetative units form fruiting structures.
2. Most eukaryotes were unicellular until the beginning of the Cambrian. The rapid diversification and increased size of multicellular eukaryotes (especially animals) near the beginning of the Cambrian led to greatly increased chances of fossilization.
 3. Examples; other answers are possible.
 - a. Alveolates: Dinoflagellates can be toxic (e.g., they can poison mollusks during red tides); the apicomplexan *Plasmodium* is the causative agent of malaria.
 - b. Stramenopiles: Some brown algae are harvested and used by humans as an emulsifier in ice cream, cosmetics, and other products.
 - c. Excavates: The parasitic *Giardia lamblia*, a diplomonad, causes the intestinal disease giardiasis (an infection common among hikers and campers who drink spring or stream water in recreational areas). Kinetoplastids include several medically important species of pathogenic trypanosomes that cause diseases such as sleeping sickness, Chagas disease, and leishmaniasis.

RECAP 26.3

1. Two paramecia exchange genetic material during conjugation, but there is no increase in the number of individuals. As a result, there is sex (genetic recombination) but no reproduction.
2. The sex that occurs in conjugation allows the removal of deleterious mutations through genetic recombination. Without conjugation, paramecia can only reproduce clonally, which is not viable over long periods of time.
3. Alternation of generations involves alternation of *multicellular, independent* haploid and diploid stages. Sperm and eggs are unicellular and are not independent organisms.

RECAP 26.4

1. The female mosquitoes transmit the *Plasmodium* parasites to vertebrate hosts. The mosquitoes take up *Plasmodium* along with blood from an infected host and transmit the parasite to new, previously uninfected hosts when they feed on the blood of the new hosts.
2. Red tides are massive blooms of free-living protists (often dinoflagellates) that occur in oceans (and sometimes freshwater bodies) around the world. Many dinoflagellates involved in red tides produce toxins that kill many other species, especially fish and other vertebrates. Dinoflagellates are important symbionts of corals; when environmental conditions change, the dinoflagellates die or are ejected from the host corals, resulting in bleaching. The corals may take up new dinoflagellates, or they may become weakened and perish.
3. Diatoms are important as primary producers in many ecosystems. Of more direct importance to humans, fossilized oils from diatoms are the primary source of petroleum and natural gas. In addition, the remains

of diatom skeletons produce diatomaceous earth, which is used for insulation, filtration, polishing, and as an insecticide.

WORK WITH THE DATA, P. 569

1. No. The new strain (B211 in this experiment) was taken up by 92 percent of the coral colonies after bleaching (and by 100% of the surviving colonies), even though at least 58 percent of the experimental colonies retained some of their original symbionts after bleaching. This shows that bleached coral colonies are likely to take up strains of *Symbiodinium* that are available in the environment, even if some of their original symbionts survive the bleaching.
2. No. Between week 3 and week 6 after bleaching, an additional 17 percent of the experimental colonies died despite having acquired new strains of *Symbiodinium*.
3. This observation suggests that the detection assays for *Symbiodinium* are not sensitive enough to detect very small levels of the symbionts. Presumably, the non-B211 strains were present in some of the experimental colonies in week 3, but at such low levels that they were not detected. These symbionts then recovered in 8 percent of the colonies and were at detectable levels by week 6. Another possibility is that contamination of the experimental samples with non-B211 symbionts took place between weeks 3 and 6 of the experiment. Neither possibility challenges the conclusion that corals can acquire new strains of *Symbiodinium* from their environment after bleaching events.

FIGURE QUESTIONS

Figure 26.1 DNA sequences of genes that are found in all genomes (such as the ribosomal RNA genes) can be used to connect organelles to their endosymbiotic ancestors. If the organelles did not evolve through endosymbiosis, then we would expect homologous copies of organellar and nuclear genes from the same species to cluster in a phylogenetic tree. However, this is not the case. Instead, phylogenetic analyses show that the ribosomal RNA genes of mitochondria in eukaryotes are more closely related to homologous genes from proteobacteria than to eukaryotes, and the ribosomal RNA genes of chloroplasts in eukaryotes are more closely related to homologous genes from cyanobacteria than to eukaryotes. These analyses provide convincing evidence in support of the endosymbiotic origins hypothesis.

Figure 26.19 Conjugation is considered sex without reproduction because genetic material is exchanged (sex) but no new *Paramecium* are produced.

APPLY WHAT YOU'VE LEARNED

1. All of the apicomplexans shown here have a parasitic lifestyle. Therefore this lifestyle was likely present in the common ancestor of the apicomplexans. The hosts of the three apicomplexans differ, but they are all mammals. Thus it is reasonable to infer that the common ancestor of these species likely had a mammalian host.
2. No, all of the dinoflagellates are equally distantly related to the apicomplexans, so there is no reason to favor one genus over another in choosing an outgroup.
3. The genus *Alexandrium* is more closely related to *Pfiesteria* than to any of the other genera, so this genus is a good choice for comparison, as the two genera share the most recent common ancestor. Therefore comparing *Alexandrium* to *Pfiesteria* would help the investigator determine which attributes evolved in *Pfiesteria*, and which were already present in the common ancestor of *Alexandrium* and *Pfiesteria*.
4. Answers will vary. One example is the morphological similarity of loboceans and heteroloboceans, despite these groups not being closely related.

Chapter 27

RECAP 27.1

1. The broadest use of the term “plant” refers to eukaryotes that descended from the ancestor with the first primary endosymbiosis of chloroplasts: glaucophytes, red algae, the various lineages of green algae, and land plants. Another use of the term refers to green plants (those that contain chlorophyll *b*, or the green algae and land plants). The most common use of “plant” refers only to land plants.
2. “Algae” is a convenience term that is used to refer to many distantly related, photo-synthetic, aquatic organisms. This includes many groups of eukaryotes outside the Plantae.
3. Glaucophytes are unicellular and also differ from the other groups because their chloroplasts contain a small amount of peptidoglycan between the inner and outer membranes. Most red and green algae are multicellular. Red algae contain an accessory photosynthetic pigment (phycoerythrin), which often gives them a red color, especially in deeper water. The green algae lack phycoerythrin but have a second kind of chlorophyll (chlorophyll *b*) in addition to chlorophyll *a*, which is also found in glaucophytes and red algae.
4. Both land plants and green algae contain chlorophyll *b* in addition to the chlorophyll *a* also found in

glaucophytes and red algae. Land plants are more closely related to some green algae lineages than to others. The green algae most closely related to the land plants are the stoneworts; these two groups share protected embryos, a cuticle, a multicellular sporophyte, the presence of gametangia, and thick-walled spores.

RECAP 27.2

1. Alternation of generations is a life cycle in which a multicellular diploid sporophyte generation produces spores by meiosis, alternating with a multicellular haploid gametophyte generation that produces gametes by mitosis. Humans (and other animals) do not have alternating sexual and asexual multicellular stages. They undergo meiosis to produce sex cells and use mitosis for growth and maintenance, not for reproduction.
2. Terrestrial adaptations found in all major lineages of land plants (including liverworts, mosses, and hornworts) include the cuticle, which provides a coating of waxy lipids that retards water loss; gametangia (multicellular organs that enclose plant gametes), which prevent gametes from drying out; protected embryos; pigments that provide protection against ultraviolet radiation; thick-walled spores; and a mutually beneficial association with fungi that promotes nutrient uptake from the soil. Stomata, which are small closable openings in leaves and stems that are used to regulate gas exchange, are a terrestrial adaptation that is found in all land plants except liverworts.

RECAP 27.3

1. Xylem conducts water and minerals from the soil to aerial parts of the plant. Xylem also provides structural support. Phloem conducts the products of photosynthesis from sites of production to sites of storage within the plant.
2. The earliest rootlike structures were rhizomes—horizontal portions of stem that bear water-absorbing filaments called rhizoids. Rhizomes are retained in some modern plants, such as liverworts and mosses, and are also found in some vascular plants, such as ferns and lycophytes. Ferns and lycophytes, along with other vascular plants, also have true roots, a specialized organ for extracting water and minerals from the soil. Leaves may have originated twice among the vascular plants. The simple microphylls of lycophytes may have arisen from sterile sporangia. In contrast, the larger and more complex megaphylls, or true leaves, may have arisen from the flattening of a portion of a branching stem system that exhibited overtopping growth.
3. Heterospory refers to the presence of two distinct types of spores, one that develops into a female gametophyte and the other into a male gametophyte. One advantage of heterospory is that it promotes outcrossing among individuals. The fact that heterospory has evolved multiple times from homospory provides evidence that the heterosporous condition is advantageous.

WORK WITH DATA, P. 574

1.

2. Changes for each branch are indicated on the tree diagram provided with the answer to Question 1. Note that there are alternative (equally parsimonious) reconstructions for character numbers 6, 14, and 16.
3. Characters 7 and 19 exhibit homoplasy.
4. These groups are labeled in the figure provided as the answer to Question 1.

WORK WITH DATA, [P. 576](#)

1. The 95% confidence intervals for the means can be calculated by multiplying the standard errors of the means by 1.96, and then adding and subtracting this product from the respective mean.

Growth medium only	Growth medium + propionate	Growth medium + acetate	Growth medium + citrate	Growth medium + sucrose	Growth medium + glucose
10.98–15.84	1.66–1.78	7.79–11.01	14.10–16.42	15.94–19.32	29.84–44.58

Chlorophyll a concentrations in growth medium + propionate are clearly lower than in growth medium alone, as the 95% confidence intervals do not overlap. There is almost no overlap between the growth medium only and growth medium + acetate conditions, with the added acetate showing lower chlorophyll a concentrations. There is substantial overlap in the confidence intervals for growth medium alone and growth medium + citrate, suggesting no significant difference in those two conditions. The other two conditions, with sucrose or glucose added to the growth medium, result in significantly higher chlorophyll a concentrations than does growth medium alone.

2.

The measures of chlorophyll a concentration and biomass are strongly correlated, whereas cell counts are not as strongly correlated with these other measures. The reason is that favorable growth conditions produce large cells (with greater biomass) that contain proportionally more chlorophyll a, whereas poor growth conditions produce small cells that contain proportionally less chlorophyll a. Although poor growth conditions sometimes result in fewer cells than favorable growth conditions, the growth conditions have a greater effect on cell size than on cell numbers.

FIGURE QUESTIONS

Figure 27.1 The terms “algae” and “nonvascular plants” are both convenience terms, as neither of those groups forms a monophyletic group.

Figure 27.6 In plants, the haploid portion of the life cycle involves a multicellular organism, whereas in animals it involves only single-celled gametes.

Investigating Life Experiment The algae grow best in 50% wastewater and 50% growth medium.

APPLY WHAT YOU’VE LEARNED

1. The last common ancestor of seed plants and ferns lived in the mid-Devonian about 390 million years ago.
2. Spikemosses did not exist until the late Devonian. Spikemosses were not yet present when the last common ancestor of seed plants and ferns lived and thus fossils of spikemosses would not be expected in the same stratum with fossils of the common ancestors of ferns and seed plants. Because the common ancestor of ferns and seed plants lived before spikemosses did, we would expect fossils of that ancestor to be in a lower stratum.
3. Yes, rhyniophytes existed from the late Silurian through much of the Devonian, and survived for tens of millions of years after the last common ancestor of seed plants and ferns lived. So it would not be surprising if fossils of these two lineages were in the same stratum.
4. The last common ancestor of embryophytes lived in the Ordovician about 470 million years ago. This lineage was the first group of plants to live out of water and colonize land.

Chapter 28

RECAP 28.1

1. Pollen grains are highly resistant to dehydration and can be carried by wind or pollinators. Once a pollen grain lands on a stigma of a flower, it can grow a pollen tube, from which it releases sperm directly to the megagametophyte.
2. Seeds protect the embryo from excessive drying and from predators. Seeds can remain in a resting state in soil, often for many years, until conditions become favorable for growth. Many seeds also aid in dispersal by wind, water, or animals. When growth begins, the seed provides the developing sporophyte with the food reserves it needs.
3. Wood provided structural stability for the stems of plants and allowed them to reach great heights. The forests of the world are able to exist because of this evolutionary innovation.

RECAP 28.2

1. Some plants require fire for seeds to be released. For example, fire is needed to open the tightly closed cones and release the seeds of some pines, which are then able to germinate.
2. The megagametophyte is the female gametophyte, or multicellular haploid tissue contained within the ovary of all seed plants. The pollen grain is the multicellular male gametophyte, which produces the sperm that fertilize the megagametophyte.
3. These fleshy cones serve to attract animals, much as the fruits of flowering plants do. The animals eat the fleshy cones and the seeds they contain, and the seeds pass through the digestive tracts of the animals and are dispersed by their feces.

RECAP 28.3

1. One sperm produces the diploid zygote, and another produces the (usually) triploid endosperm that will provide nourishment for the developing embryo.
2. Pollination refers to the arrival of pollen on a stigma. After the pollen produces a pollen tube, it releases sperm to the megagametophyte, resulting in fertilization.
3. Fruits that attract animals to a food resource often have a fleshy, edible ovary. Animals gather or eat the fruit, and the seeds may pass through the digestive tract alive and germinate after they are deposited in the animal’s stool. In some cases, such as tree nuts, the seeds are themselves edible, and the fruit serves as a hard, protective covering. Animals such as squirrels gather the nuts, eat some, and store others for later. Some of the stored nuts then germinate into new plants. In contrast, some seeds have sticky surfaces that adhere to animals that brush by the fruiting plant. If you have ever had to pull burrs off your clothes or your pet, you have pulled out fruits of plants that are being dispersed in this manner.
4. Flowers are the site of pollination and fertilization and, in many species, serve to attract pollinators. Fruits may provide protection or means of dispersal for the seeds; often, the fruits are attractive to an animal that then disperses the seeds in its feces. The seeds protect the developing embryos until conditions are favorable for germination.

RECAP 28.4

1. There are many possible answers, some of which are shown below.

Product	Plant Source	Medical Application
Atropine	Belladonna	Dilate pupils for eye examination
Bromelain	Pineapple stem	Control tissue inflammation
Digitalin	Foxglove	Strengthen heart muscle contraction
Ephedrine	Ephedra	Ease nasal congestion
Menthol	Japanese mint	Relieve coughing
Morphine	Opium poppy	Relieve pain
Quinine	Cinchona bark	Treat malaria
Taxol	Pacific yew	Treat ovarian and breast cancers
Tubocurarine	Curare plant	Muscle relaxant (used in surgery)
Vincristine	Periwinkle	Treat leukemia and lymphoma

2. Among the possible answers: Plants produce oxygen and remove carbon dioxide from the atmosphere, and they play important roles in forming soils and renewing soil fertility. Plant roots help hold soil in place, providing protection against erosion by wind and water. Plants also moderate the local climate in various ways, such as by increasing humidity, providing shade, and blocking wind.
3. Grasses produce the grain crops (including rice, wheat, and corn) that account for a large percentage of the calories in human diets. Grasses are also the basis for feeding grazing animals, such as cattle, which provide humans with meat and dairy products.

WORK WITH THE DATA, P. 596

1.

2. One approach to this problem is to calculate a linear trend line for survivorship of *Verbascum blattaria* seeds by calculating a linear regression line (see [Appendix B](#)) and then projecting it forward in time to the point at which it intersects zero percent survival. The resulting regression equation is $y = 102.09 - 0.62x$. The graph plotted in answering Question 1 uses this approach and predicts that the last *Verbascum blattaria* seeds should germinate in about year 165 of the experiment (set y to 0, and solve for x using the regression equation; the result is $x = 164.7$ years). This approach assumes a linear decline in viability of the seeds. It may be more reasonable to assume an exponential decay in seed viability (similar to radioactive decay; see [Figure 24.1](#)). If seeds decay exponentially, then we would expect some low level of survivorship of *Verbascum blattaria* seeds well beyond year 165.
3. At least four factors are related to seed survivorship:
- Size of the seed: larger seeds have more food reserves (endosperm).
 - Thickness of the seed coat: thicker seed coats provide better protection of the seed.
 - Density of the seed coat: tougher seed coats provide better protection of the seed.
 - Level of dormancy of the embryos: deeper dormancy results in longer survivorship.

FIGURE QUESTIONS

Figure 28.2 The haploid gametophyte stage of the moss is the most prominent stage, and the stage we recognize most readily as a moss. The haploid stage of ferns, in contrast, is very inconspicuous, so we usually see the larger diploid sporophyte. In flowering plants, the haploid gametophytes are rarely seen, except as pollen.

Figure 28.17 Although rodents destroy the seeds of nut-bearing plants when they eat them, these plants produce far more nuts than rodents can immediately eat. Rodents gather extra nuts and stash them for later consumption in or around their nests, often burying them in soil in the process. Many of these extra nuts then germinate before they are consumed by the rodents.

APPLY WHAT YOU'VE LEARNED

1. The bright red color of *M. cardinalis* flowers is consistent with the expectations of a bird-pollinated species. The nectar guides (stripes on the petals) of *M. lewisii* flowers are consistent with the expectations of a bee-pollinated species.
2. The corolla of *M. cardinalis* is narrow and tubelike, while that of *M. lewisii* is broader and flatter. The

narrow tubular corolla of *M. cardinalis* is an adaptation that accommodates the long beaks and tongues of its hummingbird pollinators, while restricting pollination by other species.

3. Variation at the *yup* locus did not significantly affect visitation by hummingbirds, but bees were much less likely to visit the CC genotype (red) flowers.
4. Although birds showed a slightly higher preference for red flowers over pink flowers, the difference shown here is not statistically significant. However, bees visit red flowers at a significantly lower rate than pink flowers. It may be that the primary function of red flowers is to discourage visitations by bees so that pollination is restricted to hummingbirds.

Chapter 29

RECAP 29.1

1. Unicellular fungi absorb nutrients directly from their environment, but multicellular fungi use structures known as hyphae for absorption. In both cases, fungi secrete digestive enzymes into the environment and then absorb the breakdown products through their cell membranes. The hyphae of multicellular fungi are long, thin networks that can penetrate soil and decaying or living organic material.
2. The large surface area-to-volume ratio allows rapid absorption over a wide area, as the hyphae can be immediately adjacent to the food source. However, this can also lead to rapid water loss and drying, which is why fungi tend to be restricted to (or at least thrive best in) moist environments.

RECAP 29.2

1. Fungi break down organic matter, especially the cellulose and lignin of plant walls, thus returning the carbon in dead plants back into a form that can be used again by other organisms. Fungi also break down the keratin of animals, which is resistant to bacterial decay. Without fungi, these materials would build up in the environment and be a global sink for carbon.
2. Lichens represent a mutualistic association between a fungus and a photosynthetic partner (a unicellular alga and/or a cyanobacterium). The fungus obtains fixed carbon (organic compounds) from its photosynthetic partner and provides it with minerals and water. Both the fungus and the photosynthetic partner benefit and can grow in harsh environments (such as on rocks or the bark of trees) where neither organism would survive well, if at all, on its own.
3. As with lichen associations, mycorrhizal fungi form a mutualistic partnership with a photosynthetic species, in this case a multicellular plant. Many plants depend on these mycorrhizal associations for survival. The plant provides organic compounds (the products of photosynthesis) to the fungus, and the fungus provides minerals and water from the soil to the plant. The high surface area-to-volume ratio of the fungal hyphae greatly increases the plant's ability to absorb water and minerals. Also, the hyphae act like a sponge, holding water around the roots

RECAP 29.3

1. In mating types, there is no phenotypic distinction as exists between male and female sexes, and there are often more than two mating types. Mating types are morphologically indistinct, but within each species, each mating type is genetically different. Individuals within a species may not mate with another of the same mating type. In contrast, male and female sexes are defined by the relative size of their gametes. (Females have large gametes, and males have small gametes; reproduction requires the combination of a male and a female gamete)
2. Microsporidia are among the smallest eukaryotes known. They are obligate parasites on animals. The host cell is penetrated by a polar tube through which the contents of the spore are injected into the host. This sporoplasm then replicates within the host cell and produces new infective spores. In some insects, once an individual is infected, the microsporidian parasite may be transmitted from parent to offspring.
3. Most chytrids possess flagellated gametes and reproduce in water (or at least in wet environments, such as moist soil).
4. The zygospore is the diploid phase of the zygospore fungi life cycle. It has a thick, multilayer cell wall and can serve as a resting stage that may remain dormant for months until environmental conditions are favorable for growth. At that time, its diploid nuclei undergo meiosis, and the zygospore produces a stalked sporangio-phore, which bears from one to many sporangia. Each sporangium contains haploid spores, which are the products of meiosis.
5. The haploid ascospores of sac fungi are contained in sacs known as asci. Many species of sac fungi bear these asci on cup-shaped fruiting bodies known as asco-ma. In contrast to these cup-shaped fruiting bodies, the fruiting bodies of club fungi include the more familiar mushrooms, puffballs, and bracket fungi, which are called basidiomata. These basidiomata bear the basidia, in which fertilization and meiosis take place to produce the haploid basidiospores.

RECAP 29.4

1. Some fungi are eaten directly (including mushrooms and a few lichens), but fungi play a bigger role in the production of bread (from baker's yeast), cheese (fungi give many cheeses their distinctive flavors), and drinks (through fermentation of yeasts). In addition, fungi enhance and facilitate the growth of many crop plants.
2. The museum lichen collections represent an indirect record of past air quality that can be used in areas where no direct measurements of air quality were originally taken. In addition, lichen diversity surveys represent a fast and inexpensive way to monitor air quality across an environment.
3. Site 5 shows the highest diversity and density of lichens and so is probably farthest from the city center. Site 4 is next, followed by Site 1, then Site 3, and finally Site 2. In addition to distance from the city center and prevailing wind direction, other predictive factors could include distance to point-pollution sources (such as factories or power plants) and distance to major highways (a source of pollution from automobile exhaust). Other answers are also possible; it is important for such studies to control for factors such as the species of tree examined and the exposure of the branches to similar light and humidity conditions.
4. By using selective tree harvest, rather than clear-cutting, forests may be managed to retain largely intact communities of many organisms, including mycorrhizal fungi. If some of the original forest trees are retained, replacement of harvested trees is greatly facilitated by the continued presence of viable mycorrhizal fungal communities.

WORK WITH THE DATA, [P. 631](#)

1.

2. Yes, the levels of environmental lead contamination and the ratios of lead isotopes are consistent with the identified sources. The closure of the lead smelter was offset by the use of leaded gasoline, but there was a marked drop-off of environmental lead contamination after the elimination of both of these sources. The trend lines show a peak in environmental lead contamination around the 1960s to 1980s, and then a rapid drop after the end of leaded gasoline use in the early 1980s. The measured ratios of $^{206}\text{Pb}/^{207}\text{Pb}$ are consistent with the suspected sources of lead contamination through time. One way to extend the analysis would be to analyze additional lichen samples collected during the relatively poorly sampled period between 1907 and 1978 (from which period only two samples are included). Note, however, that such an analysis would depend on the existence of appropriate samples, such as museum collections made during this time.

FIGURE QUESTIONS

Figure 29.15 The two gametes differ in size; a male gamete is defined as the smaller of the two gametes, and the female is the larger gamete.

Figure 29.17 In the dikaryotic state, each cell contains a separate haploid nucleus from each parent. In the diploid state, the two nuclei are fused.

APPLY WHAT YOU'VE LEARNED

1. There is a strong linear relationship between the negative effects of exposure to garlic mustard on a

species and its dependence on its fungal mutualists, as the plants that are most dependent on the mutualism are most negatively affected by exposure to garlic mustard. This is consistent with garlic mustard reducing growth by interfering with the mycorrhizal mutualists.

2. Trees from mature forests are most dependent on arbuscular mycorrhizal fungi. A reasonable explanation for this finding is that trees in mature forests rely heavily on drawing nutrients and water from their roots, the site of action for arbuscular mycorrhizal fungi. Plants that live on forest edges and particularly those that live in disturbed areas are less reliant on the mutualists than are those that live in mature forests. This may be due to edge species being less reliant on gathering water and nutrients via their roots.
3. Plants with active arbuscular mycorrhizal fungal mutualists are more resilient to drought and temperature extremes than those without. Thus the loss of the fungal mutualists by exposure to garlic mustard may lead to the plants being less resilient to drought and temperature extremes.
The plants with arbuscular mycorrhizal fungi should be able to withstand extremes in climate better than those without. Loss of fungal mutualists via the action of garlic mustard should lead to greater negative consequences for the plants as a result of climate change.

Chapter 30

RECAP 30.1

1. Most animals are multicellular heterotrophs with internal digestion, muscular systems that allow movement, and nervous systems. This combination of features generally allows us to distinguish animals from other groups, although none of these features is diagnostic (by itself) for all animals. Other groups (such as protists, fungi, and plants) include multicellular species; many protists and fungi are heterotrophs; some protists have internal digestion; and not all animals have muscular systems and nervous systems. Evidence for the monophyly of animals comes from gene sequences, as well as a few microstructural features: a common set of extracellular matrix molecules, including collagen and proteoglycans; and unique types of junctions between cells (tight junctions, desmosomes, and gap junctions).
- 2a. In radial symmetry, body parts are symmetrical across multiple planes that run through a single axis at the body's center. Animals with radial symmetry have no front or rear ends, and they are often sessile or drift freely with currents. If they move under their own power, they can typically move slowly equally well in any direction. In contrast, bilaterally symmetrical animals have mirror-image right and left halves divided by a single plane that runs along an anterior-posterior midline. They have front ends that usually contain a concentration of sensory systems and nervous tissues in a distinct head. Bilaterally symmetrical animals usually move forward in the direction of the head, so that the head encounters new environments first.
- b. Among the bilaterian animals, there are two distinct forms of gastrulation—the initial indentation of a hollow sphere of cells early in development that forms the blastopore. In protostomes the blastopore eventually develops into the mouth of the animal, whereas in deuterostomes the blastopore becomes the anus.
- c. Diploblastic animals have embryos with two cell layers (an outer ectoderm and an inner endoderm). The embryos of triploblastic animals have an additional cell layer between the ectoderm and the endoderm, known as mesoderm.

RECAP 30.2

1. Bilaterally symmetrical organisms have an anterior and a posterior end. As the animal moves through the environment, its anterior end encounters potential food or predators first. It is therefore advantageous for the sensory organs and central nervous system to be concentrated at the anterior end.
2. The body cavities of many animals function as hydrostatic skeletons. As the muscles that surround a cavity contract, the fluids must shift to another part of the cavity. In this way, animals can extend parts of their bodies and move specific body parts. Segmentation allows specialization of the body parts, and soft-bodied animals can change the shape of each part independently, thereby increasing the precision of movement. In animals with a hard external skeleton (such as the arthropods), segmentation and the accompanying appendages (controlled by muscles attached to the exoskeleton) allow even greater specialization of movement. Some arthropod appendages are used for walking, swimming, and even flying. The central nervous system is used to sense the environment (including food, appropriate temperatures, and potential predators) and to coordinate movement.
Acoelomate animals lack a body cavity enclosed in mesoderm. Pseudocoelomate animals have a body cavity enclosed in mesoderm; this body cavity contains the gut and internal organs composed of endoderm, but these latter organs are not lined with mesoderm. Coelomate animals have a body cavity that is enclosed in mesoderm, and the internal organs are also lined with mesoderm.

RECAP 30.3

1. Filter feeders filter water or air and trap small food particles they contain. These particles may include

small animals, but the filter feeder does not typically actively chase and feed on individual prey. Predators, in contrast, actively seek out and feed on other individual animals, killing them in the process. Parasites also feed on other animals, usually without killing them; a parasite may reside inside another animal or feed on its parts from the outside (such as a mosquito or a tick does).

2. Herbivores must digest relatively fibrous, tough plant material. So they usually need a longer gut (compared with carnivores) or a digestive system that permits fermentation of plant material. They usually need mouthparts that allow chewing of leaves or sucking of plant fluids. A predator needs to be able to move quickly enough to catch its prey and needs adaptations for subduing the prey (such as teeth, jaws, claws, venom, constriction, etc.).

RECAP 30.4

1. In a multicellular organism, every cell has the same genotype, and the cells are all physiologically interconnected and interdependent to form one functioning organism. In a colonial species, the individuals are more loosely integrated with one another, and individuals that make up a colony may also be able to exist independently of one another. In some cases, different individuals in a colony have different genotypes, although some colonies may be composed of clonally duplicated organisms that function as an integrated whole. Every individual in a colony is typically multicellular, unlike the single cells in a multicellular individual.
2. Typically the characteristics of an animal in one life stage are beneficial under certain conditions but detrimental under others. A change that improves one characteristic, such as a thicker shell for protection against predation, usually comes at a cost of some kind, such as less mobility. In a life cycle, an animal may evolve to produce more eggs, but that usually comes at a cost of the investment of resources in each egg, which leads to lower survivorship of the average offspring. For this reason, there are limits on the changes that can occur in the evolution of life cycles.

RECAP 30.5

1. First, phylogenetic analysis showed that ctenophores were the sister group of other animals. Ctenophores have nervous systems, but some other animals (such as sponges and placozoans) do not. Therefore either nervous systems evolved once in the ancestor of all animals and were subsequently lost in sponges and placozoans, or nervous systems evolved separately in ctenophores and in other animals. Second, analysis of whole genomes showed that the genes involved in nervous systems have been independently duplicated and specialized in ctenophores, cnidarians, and bilaterians, thereby suggesting that the nerve nets of ctenophores and cnidarians, and the centralized nervous systems of bilaterians, each evolved independently.
2. The group of organisms called “animals” represents a specific monophyletic group of multicellular organisms on the tree of life. Sponges retain many of the ancestral features of animal relatives (such as choanoflagellates), and split from the other animals before the evolution of complex organ systems. Placozoans, by contrast, may have evolved from ancestors with distinct organ systems, but they appear to have lost these systems and become secondarily simplified.
3. Placement of glass microscope slides (or other smooth substrates for placozoan attachment) in warm tropical waters often results in colonization by placozoans. The glass slides can be suspended in water in survey areas, then later retrieved and examined for the presence of placozoans.

WORK WITH THE DATA, [P. 650](#)

1.

2. Refer to figure above. The number of changes is shown on the tree for each branch; each arrow shows one change.
3. Amino acid positions 5 and 6, both of which exhibit the same state in ctenophores and the outgroup, but a derived state in the remaining animals, support the ctenophores as the sister group of the remaining animals.
4. Each of these groups is marked on the tree above (answer to Question 1).

FIGURE QUESTIONS

Figure 30.1 Nervous systems are shown evolving three times: nerve nets in ctenophores and in cnidarians, and central nervous systems in bilaterians.

Figure 30.14 Producing many small eggs allows a species to rapidly expand its population size under favorable environmental conditions. However, when conditions are less favorable, the low parental investment in each egg means that very few, if any, offspring are likely to survive. In contrast, producing one large egg with high parental investment greatly increases the likelihood of each offspring surviving, but many fewer offspring can be produced, so populations cannot change rapidly to take advantage of temporarily favorable conditions.

APPLY WHAT YOU'VE LEARNED

1. Based on these data, the chemical disturbance of CsCl induced reverse development as compared with the control population. Increasing concentrations of CsCl resulted in stronger reverse development, as evidenced by the higher percentages of animals in polyp and reducing medusa stages in response to increasing concentrations of CsCl. Reverse development allows for some cnidarians to survive periods that are not suitable for their survival and reproduction as medusae.
2. The medusa form is motile and sexual, while the polyp form is sessile and asexual. Disadvantages associated with reverse development include decreased outbreeding opportunities, decreased dispersal, and investment in reverse development that could otherwise be devoted to maintenance or reproduction.

as a sexual medusa. These negative trade-offs are tolerated because reverse development allows survival in an environment that is not suitable for medusae.

3. Yes, you would expect the two populations to look different. Polyps promote survival and maintenance of local populations because they can reproduce without a mate, but they limit the ability to disperse. Medusae may enhance dispersal probability and/or population expansion and increase genetic diversity, but medusae are more energetically expensive, and developing and maintaining reproductive structures can be costly. So when conditions are good (high food abundance), it is favorable to be a sexual, motile medusa, and when conditions are poor (low food abundance), it is favorable to be an asexual, sessile polyp.

Chapter 31

RECAP 31.1

1. A soft body covering maximizes flexibility and body conformation, allows movement into confined spaces, and permits direct exchange of gases and fluids with the environment. Movement of soft-bodied organisms is largely through the actions of muscles acting on a hydrostatic skeleton. A hard body covering, in contrast, provides greater protection from predation and dehydration and provides a structure to anchor muscles that attach to appendages, which can assist in movement and feeding. Respiration in a hard-bodied organism must be accomplished through external openings and movement of gases inside the body.
2. Their jointed appendages and rigid exoskeletons provide support for walking on land. The exoskeletons also provide protection against dehydration, which is important in a terrestrial environment.

RECAP 31.2

1. The dorsoventrally flattened body of flatworms ensures that each cell is near a body surface to allow gas exchange directly with the surface. In addition, the highly branched gut increases the surface area for transfer of nutrients to the nearby cells.
2. Most annelids have a thin, permeable body wall that serves as a surface for gas exchange. Annelids rapidly lose water across this body wall if they are removed from moist environments.
3. The basic body organization of a mollusk includes a muscular foot, a visceral mass, and a mantle that typically secretes a hard, calcareous shell. The primary modifications of the major groups of mollusks have involved the foot and the shell. Over the course of evolution, the foot has been modified as a crawling structure (as in gastropods), a burrowing structure (as in bivalves), a clinging structure (as in chitons), or a sensory and feeding structure (as in the arms and tentacles of cephalopods). The shell has been modified to form a series of flexible but protective plates (as in chitons), a hinged pair of valves (as in the burrowing bivalves), a greatly reduced structure for internal support (as in many cephalopods), or a mobile, spiraling chamber to protect the visceral mass (as in gastropods).

RECAP 31.3

1. In many wormlike ecdysozoans, the cuticle is relatively thin and flexible. This provides only modest body protection and support but allows the exchange of water, gases, and minerals across the body surface. Species in which the cuticle is thin are typically restricted to moist environments. In contrast, most arthropods have a thicker, more rigid cuticle that protects against dehydration and predation and provides support for muscle attachment, which allows for colonization of drier environments.
2. Many nematodes act as scavengers in the soil and are important in decomposition and soil formation (which is critical to agriculture). The nematode *C. elegans* is an important model organism that is widely used by geneticists and developmental biologists. Other species of nematodes parasitize humans, causing diseases such as trichinosis and elephantiasis.

RECAP 31.4

1. The segmented bodies of arthropods, with rigid exoskeletons and jointed appendages, provide support for walking, swimming, and flying, so arthropods are well suited to life in many different environments. Their exoskeletons also provide protection against dehydration and predation.
2. Incomplete metamorphosis involves a series of gradual changes among instars. Complete metamorphosis involves a dramatic morphological change between two developmental stages, as between caterpillars and butterflies.
3. One factor contributing to the success of insects is that flight gives insects greater access to plants. Many insect species are specialists on one or a few plant species, and plant diversity is far greater on land and in freshwater environments than in the oceans. Although some insects live in fresh water for part or all of their life cycles, these freshwater environments are closely associated with surrounding terrestrial environments. Crustaceans have been much more successful in the oceans than have insects, and crustaceans may simply outcompete insects in marine environments.

WORK WITH THE DATA, [P. 678](#)

1. Estimates:

- Number of host-specific beetles species in the forest canopy = (Number of beetles specific to *L. seemannii*) × (Number of species of canopy trees) = $(163) \times (70) = 11,410$.
- Number of non-host-specific beetles species in the forest canopy = $1,200 - 163 = 1,037$.
- Number of beetle species on the forest floor = one-third of the number of species in the canopy (75% of beetles are in the canopy, and 25% are on the forest floor). Based on (a) and (b), there are $11,410 + 1,037 = 12,447$ species in a hectare of canopy. Therefore we can estimate $12,447/3 = 4,149$ species of beetles on a hectare of forest floor.
- Number of species of all insects other than beetles = 1.5 times the number of beetles (40% of insects are beetles, so 60% of insects are non-beetles). From (a), (b), and (c), we can estimate $11,410 + 1,037 + 4,149 = 16,596$ beetles in a hectare of Panamanian forest.
Therefore the number of insects other than beetles in a hectare of forest = $(1.5) \times (16,596) = 24,894$.
This gives a total estimate for the number of insect species in an average hectare of Panamanian forest of $16,596 + 24,894 = 41,490$.

- The estimate for the number of host-specific tropical canopy insects = $(50,000) \times (163) = 8,150,000$.
- Add 1 million for generalist and temperate canopy beetles: total beetles = $8,150,000 + 1,000,000 = 9,500,000$.
- As in Question 1, beetle species on the forest floor = one-third of the number of species in the canopy. Therefore the number of species of ground beetles = $9,500,000/3 = 3,166,667$ species.
As in Question 1, species of all insects other than beetles = 1.5 times the number of beetles. Our worldwide estimate for number of beetle species is $9,500,000 + 3,166,667 = 12,666,667$. Therefore we estimate non-beetle species diversity at $(12,666,667) \times (1.5) = 19,000,000$.
- Summing the number of species of beetles and non-beetles, we get an estimate of worldwide insect species diversity of $12,666,667 + 19,000,000 = 31,666,667$ insect species.
Note: Many biologists have debated whether Erwin's assumptions are reasonable. Clearly, each estimate is highly dependent on how representative *L. seemannii* is as a tropical forest tree. If the average tropical forest tree has many fewer host-specific beetle species than does *L. seemannii*, then these estimates would be inflated. Likewise, an overestimate of the number of tropical forest trees, or of the percentage of ground-dwelling beetles, or of the percentage of all insects that are not beetles, would lead to further inflation of the estimates. In addition, species diversity of beetles may be higher in Panama than in other areas of the tropics. However, any of these estimates could be underestimates as well.
Only about 1 million species of insects have been described by biologists worldwide to date (see Table 31.2). All entomologists agree that many more species of insects remain to be discovered, and many new species are discovered and described every year. Most entomologists currently think that Erwin's estimates were high. Each of Erwin's assumptions is now being tested; these tests require extensive work on additional species of trees, additional groups of insects, and in additional areas of the world.

FIGURE QUESTIONS

Figure 31.24 Both are three-part body plans, divided into head, thorax, and abdomen. Both crustaceans and insects have antennae and feeding appendages on the head. However, crustaceans have additional appendages growing from both the thorax and the abdomen, whereas in insects, additional appendages are limited to the thorax. In addition, crustaceans have more than three pairs of limbs on the thorax, whereas insects have three pairs of limbs on the thorax and, in most groups, two pairs of wings.

Figure 31.28 The uppermost dorsal branch on the ancestral arthropod limb is thought to have functioned in gas exchange. The *Hox* gene expression data suggest that this structure may have been homologous to the insect wing.

APPLY WHAT YOU'VE LEARNED

- The graph shows tracheal density of the insects' legs (red line) and total body (black line) plotted against body length. Researchers wanted to understand the upper limits of tracheal density as a possible limitation for insect size. The tracheal density of the leg is more limiting because it reaches the upper limit threshold at a smaller body size.
- Insects take in oxygen through pores called spiracles, which open through the exoskeleton to the outside of the body. Oxygen exchange occurs in the tracheal network, an extensive system of tubes that branch into every part of the body. All living cells in the animal are within micrometers of the tracheal network. In contrast, humans and other vertebrates transport oxygen and carbon dioxide in blood and through a network of arteries, veins, and capillaries.
- Based on the graph, one would predict that the largest living beetle could reach a body length of about 15 cm (with 95% confidence limits of about 12-22 cm). This is the approximate length at which the upper limit of tracheal leg density is reached. The largest living beetle (*T. giganteus*) is slightly bigger than the regression line would predict, but it is within the confidence limits of the prediction.

Chapter 32

RECAP 32.1

1. Deuterostomes have radial cleavage, development of the blastopore into an anus (with formation of the mouth at the opposite end of the embryo from the blastopore), and development of the coelom from mesodermal pockets that bud off from the cavity of the gastrula. However, radial cleavage is thought to be the ancestral condition for all bilaterians and not unique to deuterostomes, as it is also found among some protostomes. The development of the blastopore into an anus is unique to deuterostomes, but it may also represent the ancestral condition for bilaterians.
2. DNA sequences of many different genes provide the strongest support for the monophyly of deuterostomes.
3. The three major groups of deuterostomes are echinoderms, hemichordates, and chordates. Sea stars are echinoderms, acorn worms are hemichordates, and humans, rattlesnakes, and tunas are chordates.

RECAP 32.2

1. Echinoderm larvae have bilateral symmetry, whereas the adults have pentaradial symmetry.
2. Sea lilies and sea urchins use their mucus-covered tube feet to filter-feed by catching passing food particles, including phytoplankton. Sea cucumbers have anterior tube feet that are modified into large, sticky tentacles that can be protruded from the mouth to capture food, then withdrawn to wipe the food into the mouth. Many sea stars use their tube feet to grasp and pull open bivalves, then push their stomach into the bivalves to digest them. Like some echinoderms, hemichordates are filter-feeders, but they lack tube feet. Instead, they capture their food on a large, mucus-covered proboscis and then move the mucus and food by cilia into the mouth.

RECAP 32.3

1. Chordates are characterized by a dorsal hollow nerve cord, a post-anal tail, and a notochord. Vertebrates have an anterior skull that encloses a large brain, an internal skeleton supported by the vertebral column, internal organs that are suspended in the coelom, and a well-developed circulatory system driven by a ventral heart.
2. Hagfishes have a weak circulatory system with three accessory hearts (rather than a single, large heart). They have only a partial skull and a simpler brain than other vertebrates, and they lack separate, jointed vertebrae in their skeletal system. Because hagfishes lack fundamental traits shared by all other vertebrates, some biologists consider hagfishes to be the sister group of vertebrates, rather than a member of the vertebrates. Another possibility is that these traits in hagfishes have been secondarily lost or simplified.
3. The four appendages common to most vertebrates are the two pectoral appendages and the two pelvic appendages. In most swimming vertebrates, these appendages function as fins. They are commonly used for propulsion (especially the pectoral fins) but are also used for steering, stabilization, and manipulation of the body position in water. Among tetrapods, the appendages are often modified into limbs used for walking, running, jumping, burrowing, climbing, grasping, and manipulating objects. There have been several reversals to finlike limbs in aquatic tetrapods (several times among amphibians, turtles, birds, and mammals, for example). The pectoral limbs of tetrapods were modified into wings for powered flight in at least three different lineages (birds, bats, and the extinct pterosaurs). The limbs have been modified for gliding as well (in fishes, amphibians, lizards, and mammals). One or both pairs of appendages have been lost or greatly reduced in many groups of fish, amphibians, reptiles (including birds), and mammals. Some well-known examples of limb reduction or loss include the completely legless caecilians and snakes, the loss of external hindlimbs in whales and manatees, and the greatly reduced forelimbs of flightless birds.

RECAP 32.4

1. Amphibians exchange gases and fluids through their permeable skin, which makes them highly vulnerable to many environmental toxins and some pathogens (especially an introduced chytrid fungus). Many species of amphibians have a biphasic life cycle, so they are vulnerable to habitat degradation and loss of both aquatic and terrestrial environments. Most amphibians do not move long distances, so they do not easily move into new habitats when their local environment is destroyed. For these reasons, they are also sensitive to rapid climate changes. Many species of amphibians have highly specialized habitat requirements and live in very restrictive ranges. Habitat loss or change within these restricted ranges often results in extinction.
2. The major mammal lineages rapidly diversified after the mass extinction event at the Cretaceous-Tertiary boundary. The extinction of many large lineages of dinosaurs may have opened up opportunities for mammalian diversification. By this time, the major continents had separated by continental drift, so there were independent radiations of mammals in Laurasia, Africa, South America, Europe, and southeastern

Asia.

3. Fossil remains of extinct theropod dinosaurs show that many features once thought to be restricted to birds, such as feathers, actually evolved much earlier among the theropods. Other typical “bird” morphological features, such as air-filled bones and a furcula (wishbone), are also typical of the larger group of theropods. Among living reptiles, DNA sequence analyses clearly unite birds with the crocodilians (the other living archosaurs). The combined evidence from many sources that birds are a surviving group of theropod dinosaurs is now overwhelming.
4. Hair evolved in the ancestor of mammals; feathers evolved among theropod dinosaurs (seen today among the birds). Among the living tetrapods, birds and mammals are endothermic. Hair and feathers provide body insulation for mammals and birds, respectively. Without these forms of insulation, the maintenance of metabolic body heat would be difficult. Fossil evidence shows that many extinct theropod dinosaurs also had feathers, so many paleobiologists predict that they were endothermic as well. Endothermy would also be expected in large, active predators—a description that fits our current view of many theropod dinosaurs.

RECAP 32.5

1. New World monkeys are all arboreal, and most have a long, prehensile tail that they use to grasp branches in climbing. Many Old World monkeys are more terrestrial, and they all lack a prehensile tail.
2. Changes in a regulatory gene that affects skull development resulted in delayed somatic development in humans (neoteny). This led to the evolution of adult human skulls that are shaped more like those of juveniles (with relatively large brains and small jaws). Thus the human skull increased in size without changing as much in shape as occurs in our closest relatives, the chimpanzees.

WORK WITH THE DATA , P. 700

1.

The minimum number of changes is two, one of which is a reversal from viviparity to oviparity.

2.

Four changes from oviparity to viviparity are required, or two additional transitions in reproductive mode compared with the answer to Question 1.

FIGURE QUESTIONS

Figure 32.17 Most adult frogs are insectivorous, but insects can be very limited during early spring or the beginning of wet seasons. By reproducing in the water, frogs can take advantage of an abundant seasonal resource (algal blooms in temporary water) as a food source for their offspring. This allows the developing tadpoles to specialize on an abundant resource until they are large enough to feed on insects.

Figure 32.19 In the amniote egg, nutrition is provided by the yolk sac, and the allantois functions in gas exchange and waste collection. The chorion holds all the various membranes together with the embryo, and also functions in gas exchange. The amnion provides structural support for the developing embryo. In viviparous species, the placenta provides nutrition, as well as gas and waste exchange, through the maternal circulatory system via the umbilical cord. Note that the yolk sac and allantois are involved in the makeup of the umbilical cord (retaining their roles in nutrition, gas exchange, and waste exchange), and the amnion and chorion retain their functions of structural support.

APPLY WHAT YOU'VE LEARNED

1. In *Sceloporus* lizards, there is a general trend toward viviparity occurring in colder (blue lineage) environments, with a few exceptions, lending support for the cold-climate hypothesis. Viviparity is advantageous in cold environments because mothers can behaviorally maintain higher temperatures for developing embryos. In addition, increased maternal investment leads to larger offspring among viviparous lizards, so the young are more likely to survive the shorter growing season of cold environments.
2. Advantages of viviparity: It can keep eggs safe. Behavioral thermoregulation can keep embryos at an optimal temperature for development. Increased maternal investment results in larger offspring that are more likely to survive the shorter growing seasons of cooler environments.
Disadvantages of viviparity: If the mother dies during the gestation, all the eggs die with her. Each female produces fewer offspring. Females are encumbered with the developing embryos, which can make escape from predators harder.
Advantages of oviparity: Females are freed from the weight of eggs, so they can reproduce more often and escape faster in response to predation attempts. They can also produce larger clutches of offspring.
Disadvantages of oviparity: Developmental temperature of eggs is dependent on the nest site, which limits the temperature of development in colder environments. Females cannot continue to contribute resources to developing eggs, which results in smaller offspring.
3. In mammals, the evolution of viviparity occurred only once. In squamates, viviparity is estimated to have originated *more than* 100 times, so there is a larger sample size of independent events for testing hypotheses. The transition in mammals occurred *more than* 100 million years ago. Many of the transitions to viviparity occurred much more recently in squamates (see the *Sceloporus* phylogeny), making it easier to reconstruct the probable environmental conditions of the time.
4. (Answers will vary.) An appropriate study design should test or demonstrate that (1) females of viviparous species behaviorally thermoregulate, and internal body temperature is different from nest temperature of oviparous species, and (2) differences in incubation temperature affect the fitness of offspring. An

example study design was used by Ji et al. (2007), who submitted females of the common sun skink (*Mabuya multifasciata*) to five different thermal regimes throughout their gestation period and compared female body temperatures across the thermal regimes and to those of nongravid females. The researchers also measured phenotypic and performance traits of the offspring to assess the relationship between fitness and developmental temperature.

Chapter 33

RECAP 33.1

1. Plant organs, such as leaves and roots, have structures that allow maximal acquisition of gases and nutrients. Also, plants can grow throughout their lifetimes, enabling them to respond to environmental cues. A plant can redirect its growth to exploit opportunities in its immediate environment.
2. Plants grow throughout their lifetimes; animal organs often stop growing at adulthood. Plant cells are totipotent; in animals, only the zygote and perhaps the earliest embryonic cells are totipotent. Plant cells divide unevenly in cytokinesis to orient organ development; in animal development, cell movements are prominent.
3. Apical-basal patterns develop in plants by unequal cell division leading to differentiation between daughter cells destined for the tip, or apex, of the plant and those destined for its base in the early embryo. Radial patterns develop by cell differentiation, whereby the embryo is first a sphere and then a cylinder.
4. Without apical-basal polarity, there will be just a massive globular embryo, and root and shoot apices will fail to develop. So these organs will could arise at any place in the developing plant, or not arise at all.

RECAP 33.2

- | 1. | Tissue | Structure | Function |
|----|--------------|------------------------------------|--|
| | Parenchyma | Thin-walled, large vacuoles | Photosynthesis in leaves, storage in roots |
| | Collenchyma | Elongated, thick-walled at corners | Flexible support in petioles and stems |
| | Sclerenchyma | Thick-walled, bundles | Support of stems, occurs in fruits |
2. Collenchyma has primary walls at the corners of cells and is somewhat flexible; sclerenchyma has thick, less-flexible secondary walls.
 3. When tracheids die, pits in their walls remain and allow water to flow between the cells. Vessel elements are long tubes, laid end-to-end, that die and form a continuous tube.

RECAP 33.3

1. An apical meristem has stem cells that continuously divide. Some of the daughter cells form new organs (e.g., leaves), but others remain to divide further as part of the undifferentiated pool.
2. Root and shoot apical meristems give rise to primary meristems, which are responsible for primary growth of plants and form all plant tissues. There are three primary meristems: (1) protoderm forms dermal tissues; (2) ground meristem forms ground tissues; and (3) procambium forms vascular tissues.
3. The root apical meristem forms the root cap and root primary meristem. The latter forms the dermal, ground, and vascular tissues of the root. The root grows by cell expansion in a region just above the root apical meristem.
4. Primary: apical meristem; secondary: lateral meristem (vascular cambium) and lateral meristem (cork cambium)
Primary: Xylem, phloem, parenchyma, dermal tissue; secondary: secondary xylem and phloem, cork
Primary: growth in length; secondary: growth in thickness

RECAP 33.4

1. Seeds of wild relatives of crop plants have genes that may have been selected against during plant domestication. These genes might encode phenotypes that adapt the plants to their wild environment but were not valuable to farmers at the time of domestication. But the environment can change, and the genes that were selected against can again become valuable. An example might be a changing climate where roots that grow deep would be advantageous. The cultivated crop may lack genes for this phenotype, but genes for root growth might still be present in a wild relative.

WORK WITH THE DATA, P. 729

1. CG appears to be highest in the upper leaves and shoot, where it is made. The lower leaves and stems contain less CG, indicating that CG is transported there on the way to other plant organs.
2. The fifth leaf accumulated CG, which was not transported down the plant vascular system because of girdling. There was some residual accumulation in the sixth leaf that had probably arrived before the girdling. The stem below the sixth leaf had very low CG, indicating the transport was blocked.

FIGURE QUESTIONS

Figure 33.3 The plane of cell division is controlled by two factors: the deposit of cell wall material by the Golgi apparatus and the orientation of microtubules that in turn orient cellulose microfibrils.

Figure 33.5 There is an asymmetry in the cell division forming basal and apical cells. In animal cells, such asymmetry is set up by uneven distribution by cytoplasmic granules that act as signals for cell fate determination.

Figure 33.6 The leaf cells contain chloroplasts and carry out photosynthesis.

Figure 33.12 Pericycle cells are differentiated yet totipotent, and can dedifferentiate to give rise to all cell types of the root.

APPLY WHAT YOU'VE LEARNED

1. The cells are incubated in radioactive thymidine for 2 hours, during which dividing cells take up the radioactive substance and incorporate it into their DNA. After the cells are removed and placed in nonradioactive thymidine, dividing cells take up the nonradioactive substance. Thus cells dividing more than 2 hours after the start of the experiment will not be labeled. As cells formed in the first 2 hours begin to elongate and mature, the cells are pushed up the root by the new cells being made. As cells move from the zone of division to the zone of elongation, the number of labeled cells in the zone of division decreases. As cells move from the zone of elongation to maturation, the number of labeled cells in the zone of elongation decreases.
2. The number of labeled cells increases first in the zone of division, then in the zone of elongation, and finally in the zone of maturation. This indicates that root cells are added at the bottom by cell division. The cells then grow and elongate the root, then finally differentiate into the various tissue types that make up the mature root. Many cells are present in the zone of division, as the initials divide. It takes time for these new daughter cells to grow and move up the root, as they are pushed by newly formed cells below them.
3. Initials in specific locations grow up from their original locations in the meristem, with the initials forming epidermal cells located on the outside, those forming the cortex inside this, and those forming transport tissues nearest the center. These regions form the protoderm, ground tissue, and procambium, which are the precursors that differentiate into all types of root tissue. As they grow upward without migrating, the tissues naturally orient into a cylinder with several layers of cells.
4. Cells in the QC divide very slowly; in this experiment, a single cell was dividing during the first 2 hours (when labeled thymidine was present), but no more division occurred after that time. There could very well have been no division during these 2 hours, as previous experiments show that corn QC cells divide only once every 170 hours. Also, the QC contains very few cells (the exact number varies by species). This indicates that it contributes only a few cells to the growing root. These few cells might replenish initial cells lost through damage or aging, without causing excess growth of root tissue. However, this experiment does not show how (or whether) cells move from the QC to the initials.

Chapter 34

RECAP 34.1

1. Plant cells swell when they take up water. The cell wall resists this swelling, causing an increase in pressure within the cell. This results in more rigid forms of the plant organs and also reduces the tendency of the plant cells to take in more water.
2. Aquaporins are proteins that form membrane channels, allowing the passage of water via osmosis. They occur in the cell membrane and vacuolar membrane. Their presence and numbers affect the rate of water movement across the membrane, from a region of higher water potential to a region of lower water potential. One would expect increased expression of aquaporins in the vacuolar membrane as the cell expands, allowing increased uptake of water and turgor pressure.
3. The apoplast lies outside the cell membrane and consists of the cell wall and intercellular spaces. The symplast is the cytoplasm of cells that can be considered as a continuous compartment if cells are connected by plasmodesmata. Water moves rapidly through the apoplast and more slowly through the symplast.

RECAP 34.2

1. A tree was cut near its base, and the upper part of the cut stem was placed in a poisonous solution. The poison rose in the tree, killing cells as it went. This indicated that the fluid could rise without the need for the root.
- 2a. Yes. The difference in water potential between the soil and the leaf (1.7 MPa) is enough to overcome gravity and draw water to the top of the tree.
- b. No. If the soil water potential decreased to -1.0 MPa, it would be more negative than inside the root cells and water would leave the roots (and enter the soil).
- c. If all the stomata closed, the leaf water potential would not be as negative. This in turn would make the xylem

water potential less negative, and so on down to the roots. This would make the difference between the leaf water potential and the root water potential insufficient for water to flow from the roots to the leaves (toward a more negative water potential).

3. Transpiration evaporates water from cell walls in the leaves. This must occur because it begins the process. The increase in negative pressure potential resulting from transpiration draws more water into the cell walls and begins to exert tension (the second part of the process) on the entire water column within the xylem. Cohesion draws water molecules together and makes them “stick” It prevents water in the column from breaking, thus losing tension and failing to rise.
4. The great difference between water pressure potential in the soil and the air is sufficient to pull water upward through the xylem, as water evaporates into the air. This is evidence for transpiration. The continuous column of water moving upward through the xylem is evidence for cohesion. Cut stems show high negative pressure potentials, showing that the xylem is under considerable tension.

RECAP 34.3

1. In sunlight, an H^+ pump in the cell membrane of guard cells pumps H^+ out of the cells. This sets up an electrochemical gradient across the guard cell membrane and K^+ enters the cells. This in turn sets up an osmotic gradient and water enters the guard cells, causing them to become turgid and a gap to appear between adjacent guard cells. This gap is an open stoma. In darkness, the proton pump becomes less active, K^+ diffuses passively out of the cell, and the stoma closes.
2. On a hot, dry day, mesophyll cells lose water and this results in stomatal closure. Stomata remain open on cooler, humid days.

RECAP 34.4

1. A source is an organ that produces more carbohydrates than it requires. Sources can be photosynthetic (e.g., leaves) or storage organs with starch (e.g., seeds). A sink is an organ that does not produce enough carbohydrates for its own use and must import them from a source. Examples of sinks include roots and flowers.
2. Source cells load sucrose into sieve tubes of the phloem, decreasing their water potential. Water from adjacent xylem vessels enters the sieve tubes. This results in pressure inside the tubes, so the sap flows. At the sink, sucrose is removed, so the water potential inside the tubes increases. Water leaves to enter the xylem. The combination of these two events causes pressure flow.

WORK WITH THE DATA, P. 742

1. There was increased water-use efficiency (biomass accumulation divided by transpiration) in plants overexpressing *HARDY* because there was decreased transpiration (line 2) and increased photosynthesis-carbon fixation (line 3).
2. Use a *t*-test for paired samples.

FIGURE QUESTIONS

Figure 34.3 A hypertonic environment (a higher concentration of solutes outside than inside root cells) will result in osmosis. Plants wilt when water leaves root cells, reducing turgor pressure.

Figure 34.5 Tight junction

Figure 34.7 With high humidity, there would be reduced transpiration from the leaf. This would in turn reduce water pull from the leaf veins and in turn reduce water from the xylem and root uptake.

APPLY WHAT YOU'VE LEARNED

1. The increase in cell volume indicated that TIP may increase water permeability of the cell membrane and is therefore an aquaporin. The unrelated mRNA condition showed no increased cell volume, so the volume increase was not just due to any mRNA. The uninjected cells were controls to show that there was no natural increase when cells were placed in an environment that had increased water potential relative to the cell interior. This confirms low osmotic permeability of the frog oocytes.
2. The oocytes burst because there was a continuing uptake of water due to the plant aquaporin. No, plant cells injected with TIP mRNA would not have burst. In plant cells, the cell wall exerts turgor pressure potential that stops the cell from bursting.
3. The table shows direct measurements of increased osmotic water permeability in oocytes injected with TIP mRNA. This indicates that the increase in size shown in the figure, due to the presence of TIP in the oocyte membrane, was due to increased water flow, and in this case water flowed into the cell because the oocytes were in an environment of higher water potential (hypotonic).
4. In the apoplastic pathway, the PIPs would be most prominent in the stele and in the endodermis, where the Casparian strip prevents apoplastic movement of water. In the symplastic pathway, the PIPs would also be found in epidermal and cortical cells.
5. Use a specific stain that can visualize only PIP. Elongating cells would have increased staining in their cell membranes for PIP and in their tonoplasts for TIP.

Chapter 35

RECAP 35.1

1. Solutions that were thought to be pure were not, as they contained trace amounts of elements that could not be detected at the time. Recently developed chemical methods made it possible to detect essential elements that were not previously recognized.
2. Yellow leaves in a young plant may be the result of an iron or a sulfur deficiency; yellowness in older leaves suggests a nitrogen deficiency.

RECAP 35.2

1. Plants express specialized transporter molecules to move nutrients in soil water across root cell membranes. The more of a certain transporter that is made, the more its nutrient moves into the plant.
2. Plants can grow toward nutrients in the soil and orient stems and leaves to maximize exposure to light and air for photosynthesis.

RECAP 35.3

1. Heavy irrigation after a prolonged dry period may produce runoff of topsoil (the A horizon) and leaching of ions (especially anions) into the subsoil, making fewer nutrients available to plant roots. Converting land use from virgin deciduous forest to crops will change the composition of living organisms in the soil, as many organisms that live in association with tree roots will disappear. The soil structure and texture will also change, because roots will no longer be present to hold the soil together and make air spaces. The soil chemistry will change, because crops take up nutrients from the soils and the nutrients are removed from the system when the crops are harvested.
2. Cation exchange frees ions bound to soil particles into the soil solution, where they can enter plant roots.
3. There are no differences between organic and inorganic nitrogen fertilizers in terms of plant nutrition; both enter the plant root as nitrate NO_3^- .

RECAP 35.4

1. In both cases, the plants supply the other organism with photosynthate (e.g., sugars). Mycorrhizae supply phosphorus; bacteria in nodules supply fixed nitrogen.
2. Numerous species fix nitrogen. Loss of one species might allow populations of other species to expand and take on additional nitrogen fixation. Loss of all nitrogen-fixing species would mean that only abiotic methods (e.g., industrial methods) could be used for nitrogen fixation. Loss of nitrogen-fixing species would likely reduce overall nitrogen in the soil, meaning less would be available for plant growth.
3. The corn crop depletes the soil of nitrate. The soybeans do not require nitrate, as they have nitrogen-fixing nodules. When corn is rotated with soybeans, the soil becomes replenished with fixed nitrogen via free-living bacteria.

RECAP 35.5

1. Carnivorous plants capture animals, digest their proteins, and absorb the amino acids. The primary nutrient they acquire is nitrogen.
2. The experiment with mutant *Arabidopsis* suggests that *Arabidopsis* uses either its own or exogenous strigolactones for growth regulation and has the appropriate receptor and response mechanisms. This reinforces the idea that an ancient mechanism to attract beneficial microbes is also used for modern plant growth regulation. Or the reverse might be true: the original function of strigolactone might have been as a plant hormone, and its role in plant-microbe interactions might have evolved later.
3. Holoparasitic plants can gain reduced carbon through association with hosts, so the genes encoding photosynthesis functions are not under selection pressure, because having them would not confer any survival and reproductive advantage for the parasites. So any mutation that renders such a photosynthesis gene nonfunctional will not be deleterious.

WORK WITH THE DATA, [P. 759](#)

1.

Root colonization was maximal 315 days after spores were added. The lag time was probably due to the need for the spores to germinate and grow into hyphae that could colonize the cassava roots.

2a. Cassava root crop production was just as good with fungal spores alone (38 g) as with fertilizer alone (35 g). Adding spores to fertilizer had a positive effect (43 g).

b. A *t*-test for paired samples could be used to test for significance in differences for spores-treated and untreated experiments.

FIGURE QUESTIONS

Figure 35.5 Negatively charged ions (anions) can bind to certain soil particles that are positively charged and undergo ion exchange. But this does not occur at the pH of typical soils. For most soils with negatively charged particles, anions can leach out of the soil rapidly unless taken up by the plant roots.

Figure 35.8 O_2 is a strong oxidizing agent, and could attract electrons (and hydrogen atoms) that are needed for nitrogenase. These electrons come from a strong reducing agent.

APPLY WHAT YOU'VE LEARNED

1. Yes, some of the data support the researchers' conclusion that nickel is an essential micronutrient. Specifically, the germination data presented in the graph show that seed germination rate is related to the nickel quantity present in the seed. Seeds produced from plants grown under extremely low nickel concentrations have significantly lower germination rates than seeds produced from plants grown in higher concentrations of nickel. Because barley plants have high rates of germination failure without nickel, they cannot complete their life cycle in the absence of this nutrient. Over three generations, the plants were gradually depleted of nickel. This makes nickel an essential nutrient.
2. The data show that the mass of seeds produced by a plant is not affected by lack of nickel availability to the plant. This means that production of seeds within a parent plant occurs through processes that are not dependent on nickel. This conclusion does not contradict the conclusion from Question 1, which states that germination of seeds is dependent on nickel. Seed production within a parent plant and germination of the seed once it leaves the parent plant occur by two separate processes, only one of which is dependent on nickel.
3. Because soil is a complex mixture of organic and inorganic matter, it is more difficult to control the nutritional content of soil than it is to make a liquid growth medium with a defined and well-controlled content. The researchers would not have been able to easily remove nickel from soil and verify its nickel content. The results from using hydroponic growth conditions can be extrapolated to growth in soil because barley is able to adequately obtain the nutrients it needs from both hydroponic solutions and soil. Therefore there is no reason to think that different results would be observed using soil.

Chapter 36

RECAP 36.1

1. Fire produces ash, which enriches the soil with plant nutrients. A seed that germinates as a result of fire could have an advantage in such nutrient-rich soil. Such seeds might have a selective advantage in habitats such as forests, where periodic fires are natural events.
2. Both hormone receptors and photoreceptors are proteins that change when bound to a signal and set off a signal transduction response in a cell. Hormones are chemical in nature (such as small molecules, proteins, and steroids), whereas photoreceptors change when light binds to them.
3. Seeds would be treated with a mutagen and then planted. Those seeds that germinated immediately might have a mutation that affects dormancy. These mutant plants could be compared with wild-type

plants to isolate the genes involved.

RECAP 36.2

1. An inhibitor of mRNA translation would block the gibberellin-induced synthesis of hydrolases. A proteasome inhibitor would block the hydrolysis of the repressor that normally is broken down when gibberellin affects cells. So gibberellin signal transduction would be inhibited and there would be no increase in hydrolase synthesis. In the case of auxin and coleoptiles, without inhibitors, there would be cell expansion and coleoptile growth. These effects would not occur in the presence of mRNA translation and proteasome inhibitors.
2. Cells away from the lighted side receive more auxin. Cell elongation on the shaded side is accelerated with the input of auxin, which causes bending toward the light.
3. To test for the relationship between corn stunt spiroplasma infection and suspected inhibition of gibberellins, you could compare measurements of gibberellins in plants infected with the bacterium and in normal plants. A reduction of gibberellins in the spiroplasma-infected plants would support the hypothesis that the infection inhibits synthesis of gibberellins. Another approach would be to infect normal plants with the spiroplasma and then spray gibberellins on them. If this process reversed the stunt phenotype, it would be reasonable to conclude that the infection reduced synthesis of gibberellins.

RECAP 36.3

1. Cytokinins stimulate axillary buds to grow into branches, which would make the plant more bushy. Auxins help maintain apical dominance, which prevents branching. Thus this plant most likely has a low ratio of auxin to cytokinin.
2. The charcoal in the bag absorbs ethylene gas, which is released by ripening fruits. The lack of ethylene prevents over-ripening and decay.
3. Both ethylene and brassinosteroids promote leaf senescence, so either or both of these hormones are most likely active. Cytokinins delay leaf senescence, so they are most likely inactive in this plant.

RECAP 36.4

1. An action spectrum for the bending of coleoptiles toward light shows that blue light is most effective. Genetic screens for blue-light insensitivity have shown that there is a blue-light receptor present on normal plants that is not present in plants unable to respond to blue light.
2. Red light causes phytochrome to convert from the Pr to the P_{fr} form. The latter is active in promoting seed germination. Far-red light reduces P_{fr} by causing it to convert to Pr, which is inactive in promoting seed germination.

WORK WITH THE DATA, P. 772

1. Light was shone from the right of the observer.
2. These data indicate that the tip is necessary for bending to light (if the tip was cut off, the plant did not bend). The fact that cutting the very apex (1.27 mm) of the tip allowed some bending indicates that there was not significant injury and the plant was still functional.
3. The data indicate that exposure of the tip to light is necessary for the bending re-sponse. The six coleoptiles that bent slightly even though they were covered possibly were ineffectually covered—that is, they might have had some light leakage, like that noted for the coleoptiles where the ink on the tubes was cracked.

WORK WITH THE DATA, P. 781

- 1a. A high number means that more light energy at that wavelength is needed for the response (seed germination) than a low number.

b.

The highest efficiency was in the red part of the visible spectrum (600-680 nm).

- 2a. The photoreceptor has two forms that reversibly interconvert: red light stimulates the formation of the active receptor, and far-red light stimulates the conversion of the active receptor to its inactive form.
 - b. A small amount of phytochrome was in the P_{fr} state in the dark.

FIGURE QUESTIONS

Figure 36.2 You could collect many seeds from strains of pea plants in nature. Do not treat these seeds with a mutagen, but allow them to germinate in the dark and then expose them to ethylene.

Figure 36.5 To stimulate the breakdown of starch, seeds are imbibed in water and mashed up.

Figure 36.9 Proton pumps are present in mitochondria and chloroplasts, where they are involved in the production of a proton gradient in chemiosmotic synthesis of ATP.

Figure 36.10 Only ubiquitin and proteasome are the same. The other molecules are specific to the particular hormone. For example, there is a specific receptor for auxin and a different receptor for gibberellin.

APPLY WHAT YOU'VE LEARNED

1. Acting alone, *phyC* enhances leaf area, whereas *phyA*, *phyB*, and *phyD* do not.
2. *Arabidopsis* seeds would be treated with a mutagen and planted. Those plants with reduced leaf size would be isolated and grown to examine for *phyC* mutations.
3. The leaf area phenotypes produced by these three conditions are equal. All three groups have leaf areas about one-third smaller than that of the WT group. This suggests that (1) the *phyA* and *phyC* genes have the same effect on controlling leaf area (these results show the effect of the mutant, or nonfunctional gene, so the functional gene should increase leaf area by one-third); (2) either gene will work with equal effect in the absence of the other (shown by *phyAD* and *phyCD*); and (3) having both genes dysfunctional does not increase the effect (shown by *phyACD*).
4. A deficiency in *phyB* causes a very long leaf (a long petiole) and a very small leaf area (small leaf). This suggests that, if this gene were functional, it would control leaf growth by greatly inhibiting petiole length and greatly increasing leaf area. This would produce a leaf with a large surface area for photosynthesis, which could be highly adaptive. *PhyA* and *phyC* have the same effect on leaf area as *phyB*, but to a lesser extent. *PhyA* and *phyC* also inhibit petiole length, with *phyA* having the greater effect and *phyC* adding slightly to this effect. It is likely that, in plants in nature, the control of these two leaf features results from the ratio of the various phytochromes present.

Chapter 37

RECAP 37.1

1. The pollen tube is required to deliver the sperm cell from the stigma of the plant to the egg nucleus in the embryo sac, which is located in the ovary at the bottom of the style. Failure of the pollen tube to grow properly and reach the egg nucleus will result in failure of reproduction, including failure of seed and fruit formation.
2. In the megagametophyte, one of the original nuclei becomes an egg cell; the remainder form the protective and nutritive embryo sac. In the microgametophyte, the eight original cells from meiosis become four two-celled pollen grains, each containing a sperm cell as well as a tube cell, which forms the pollen tube. The female structure is larger and contains nutrients for the developing embryo. The pollen grains are tiny and numerous, making movement easier and pollination more likely.
3. In triploid cells undergoing meiosis, there cannot be pairing of homologous chromosomes in meiosis I, so meiosis I is abnormal and functional gametes do not form. A fruit is formed from the ovary wall of the flower. Seedless grapes are probably propagated by cuttings (vegetative reproduction).
4. All fruits protect the seed and aid in seed dispersal, but the variety of fruits means they can fulfill these functions in many different ways, depending on locations and environmental factors. Some seeds, such as many tree seeds, fall to the ground and remain near their parent. Others are much smaller and have structures (wings, burs) that enable their dispersal by wind or animals. In this way, they can move long distances, increasing their range and chances of survival.

RECAP 37.2

- 1a. The mutation stabilized the CO protein.
b. The mutation caused nonfunction of the FD protein.
c. The mutation increased expression of the FLC protein.
d. The mutation caused constitutive expression of the CO protein.
2. Long-day plants typically bloom when days are long and nights are short, as in the summer. But in a greenhouse setting, plants can be tricked into responding as though the nights are short by turning on the lights for a short time in the middle of the night (night interruption lighting). This breaks up the long night, so the plants act as though the night is short—that is, they begin to flower.
3. Examples of evidence include:
 - Spinach will not flower if the shoot is masked to imitate short days but will flower if the bud (and not the shoot) is masked.

- If a photoperiodically induced leaf is immediately removed from a plant, flowering will not occur. But if the leaf remains on the plant for several hours (allowing time for the substance to move to the bud), flowering will occur.
- In grafting experiments, if only one plant (or plant part) is induced to flower, the other will flower as well.

RECAP 37.3

1. Asexual reproduction is rapid, and it conserves the genetic adaptations of a plant. However, in asexual reproduction genetic homogeneity makes the offspring and population derived from it susceptible to a changing physical or biological environment, since the phenotypes in the population are all the same. Sexual reproduction produces genetic diversity in offspring and the population derived from it, and the phenotypic diversity makes the population adaptive in a changing environment. However, sexual reproduction is a slower process than asexual reproduction.
2. Asexual reproduction can occur without the need for pollination, producing many plants quickly. Many grow by means of stolons or rhizomes, which make them well adapted for poor or eroded soils, such as those on hillsides, or as pioneer plants in unstable soils such as sand dunes. Asexual reproduction is also adaptive in deserts, where it may be difficult for seedlings to become established.
3. Several approaches might be taken, such as a genetic screen for meiotic cells that do not separate chromosomes at anaphase I, or a search for proteins (and then their genes) that bind to SWI1 protein.

WORK WITH THE DATA, P. 796

- 1a. The plants were grown in short-night conditions so that flowering would not be induced by having a long night. The only condition that would affect flowering would be the brief light during a long night.
 - b. The data show that a 700-nm wavelength of light was effective at inducing flowering whereas a 680-nm wavelength inhibited flowering, indicating that the receptor is phytochrome. The far-red light for 8 min at 700 nm converted phytochrome to its active form, P_r.
2. During the day there is more red than far-red light, and the Pr form of phytochrome gets converted to the Pfr form. At night the Pfr converts back to Pr. This takes time; in the "No light" column, the data show that it took 8.5 hours for Pr to accumulate to sufficient concentration to promote flowering. This was delayed if red light (660 nm) was administered at the beginning of the dark period, as this converted even more Pr to Pfr. However, if far-red light (720 nm) was administered at the start of the dark period, the Pfr that had accumulated during the day got converted to the active form, Pr, which allowed flowering to occur after a shorter period in the dark (7 hours).

WORK WITH THE DATA, P. 797

1. The plants with their leaves removed did not flower. Therefore the leaf senses photoperiod and must be present for flowering to occur.
2. The receptor is in the leaf.
3. The environmental signal (photoperiod) is received only by the single treated leaf. The signal sets in motion a signaling pathway that ends in the bud at the shoot apex, where flowering is initiated. The data imply that an inducer of flowering is produced in leaves and is able to travel through the plant from the leaf to the shoot apex.

FIGURE QUESTIONS

Figure 37.3 Pollen tube growth requires loosening of the cell wall (hydrolase enzymes), deposition of new cell wall material (synthesis of cellulose and matrix poly-saccharides), expansion of the cell membrane and cell contents (involvement of the Golgi apparatus), and cell expansion (driven by osmosis from the vacuole).

APPLY WHAT YOU'VE LEARNED

1. The *gi* mutant inhibits or greatly delays flowering in the pea plant.
2. Yes, the evidence suggests that the *gi* mutant is unable to produce the floral chemical. When only the *gi* mutant is present (*gi/gi*), flowering never occurs. But whenever the WT is present, flowering does occur. This suggests that only the WT contains the floral chemical and that it is able to move in both directions (from stock to scion, or vice versa), causing the signal to reach the apex of the plant and stimulate flowering.
3. Under long-day conditions, the WT gene is expressed. It stimulates production of the FT protein that acts as a floral signal, and the plant flowers after 15-20 vegetative nodes have formed. However, the *gigas* gene is a null, or inactive, gene; it does not stimulate production of floral signal. In cases where the *gigas* gene is expressed, the plant remains vegetative; it either does not flower at all or flowers only after a long delay.

Chapter 38

RECAP 38.1

1. *Avr2* *Avr3* Healthy Healthy Diseased
Avr1 *Avr4* Healthy Healthy Healthy

2. Both general and specific immunity involve similar signaling pathways. For general immunity, the researcher could look for PAMPs on the pathogen, and a weaker response. For specific immunity, the researcher could look for gene-for-gene resistance (*Avr* genes) and programmed cell death and the formation of a necrotic lesion at the site of pathogen invasion.
3. Salicylate initiates systemic resistance. Application of this molecule at the site of a wound would trigger the production of protective PR proteins against further infection. This would be a long-term effect.

RECAP 38.2

1. It indicates that latex is important in defense against herbivores such as slugs.
2. Because nicotine is a secondary metabolite that is always present in tobacco leaves, it is a constitutive defense that can deter many herbivores. Induced responses would be triggered by herbivores that are not affected by the nicotine.
- 3a. This is an induced defense, as the frass contains an elicitor.
- b. Chemicals in the frass act as elicitors that trigger signal transduction pathways. One pathway involves changes in electric potential of the cell membrane, which is transmitted via the symplast to the whole plant. Another pathway triggers production of reactive oxygen species, which act as signaling molecules in pathways that lead to change in gene expression. Yet another pathway leads to production of jasmonate and other hormones, which trigger systemic defenses, and may even travel to neighboring plants to stimulate their defense responses.
4. Jasmonates are made in response to an elicitor from herbivory. Jasmonates can induce the synthesis of volatile molecules, which diffuse through the air to other plants or organs in the same plant.

RECAP 38.3

- 1a. The effects of reduced rainfall could include dehydration and osmotic stress. Genetic responses might include alterations in leaf anatomy, with a thicker cuticle to reduce evaporation; a more extensive root system to obtain water; and accumulation of solutes in the roots, which would reduce root water potential and result in more water uptake in dry soils.
- b. Flooding reduces the amount of O₂ available to the plants and results in reduced respiration. Genetic responses might include increased production of pneumatophores or aerenchyma to supply air to submerged plant tissues.
2. She could add genes encoding proteins that produce salt glands or genes that encode membrane proteins that store excess salt in the vacuole. Sequestering salt in the vacuole keeps it away from the rest of the cell, where it can harm chemicals and reactions. (See Key Concept 18.5 for salt-tolerant plants.)
- 3a. The lack of a plant cover would allow the accumulation of toxic ions in the soil.
- b. The genes involved might encode proteins that keep the toxic ions away from the plant cells (e.g., store the ions in glands) or away from the plant cells' cytoplasm (e.g., store the ions in vacuoles).

WORK WITH THE DATA, P. 809

1. Wild-type *Sr33* conferred rust resistance. Either a deletion mutant of *Sr33* (bar E5) or a point mutation of *Sr33* (bars E6-E9) resulted in rust susceptibility. Therefore *Sr33* can confer rust resistance.
2. Fielder with high-expressing *Sr33* was rust-resistant, while Fielder without *Sr33* was rust-susceptible. This reinforces the conclusion in the earlier experiments that *Sr33* confers resistance to wheat rust.
3. *Sr35* confers resistance in this relative of cultivated wheat.
4. *Sr35* also confers resistance in bread wheat. Therefore there are two genes that can confer resistance.

FIGURE QUESTIONS

Figure 38.1 Many human diseases are caused by pathogens. Here we suggest just one of many correct answers for each type of pathogen.

Virus: Influenza

Bacterium: Tuberculosis

Fungus: Candidiasis

Nematode worm: Hookworm

Figure 38.2 Both plant organs are exposed to all types of pathogens, although their identities may be different. So both root and leaf cells exposed to the environment would express the defense molecules.

Figure 38.3 Recognition is by shape (like a lock and key) and by chemical interactions between the molecules, such as hydrophobic interactions and ionic interactions.

Figure 38.12 LEA proteins might include chaperonins that bind to target proteins and stabilize them so

that the targeted proteins remain in their active state, and other proteins that stabilize membranes and keep them from drying out.

APPLY WHAT YOU'VE LEARNED

1. The wound alone causes the release of a large amount of nicotine. Caterpillar herbivory (which includes the production of FACs) causes slightly less nicotine to be released. This suggests that FACs might have a slight inhibiting effect on nicotine release. Nicotine is a constitutive response; it is present naturally in the tobacco plant and does not have to be induced as a result of gene expression.
2. Jasmonic acid production is stimulated by the production of elicitors when herbivory occurs. Jasmonic acid then causes changes in gene expression that lead to the production of secondary metabolites, such as protein inhibitors (see [Figure 38.5](#)). These protein inhibitors limit the effectiveness of the herbivore. Jasmonic acid differs from nicotine in that it does not directly affect the herbivore but stimulates production of another substance that has the effect (i.e., jasmonic acid is an intermediate substance).
3. The burst of jasmonic acid production is much greater with the addition of FACs from the caterpillars. This stronger response suggests that FACs are elicitors that *Nicotiana* must recognize to trigger genetically controlled defense responses in the plant.
4. Jasmonic acid triggers induced responses that limit hornworm herbivory in the tobacco plant. Ethylene suppresses nicotine production, making it easier for hornworm herbivory to occur. These are essentially opposite reactions. This could represent an example of the “evolutionary arms race” between plant and predator.

Chapter 39

RECAP 39.1

1. Cells are limited in size by whether their surface area is sufficient to meet their metabolic needs by diffusion and transport of nutrients and wastes across the cell membrane.
2. The major advantage of being multicellular is that every cell does not have to provide for all of its metabolic needs. Different cells can become specialized to perform specific functions that contribute to the survival and health of the whole organism. With that specialization comes greater efficiency. Also, multicellularity avoids the problem of the decreasing surface area-to-volume ratio that accompanies an increase in size of the organism. A third advantage is that bigger organisms can more easily avoid predation and in turn prey on smaller organisms.
3. The gut is a good example of how multiple tissue types contribute to the structure and function of an organ. Epithelial tissues provide the boundary between the gut and its lumen where food is digested, and also provide transport mechanisms for the uptake of nutrients. Muscle tissues provide the motility necessary to move the gut contents from mouth to anus. Nervous tissues control motility of the gut and also provide sensory information used to control gut functions. Connective tissues give structural integrity to the gut, and one connective tissue—blood—carries nutrients absorbed from the gut to all the other cells of the body.

RECAP 39.2

1. Maintenance of the internal environment is the primary focus of physiology of multicellular animals because the internal environment serves the needs of all the cells of the body. Cell types are specialized to contribute something to the maintenance of the internal environment, but no cell can provide for all of its own needs and therefore cannot exist alone.
2. Negative feedback is information about the regulated variable that can be compared to a set point to generate an error signal. The error signal is relayed to effector organs to bring the regulated variable back to the set point. Positive feedback is information about the regulated variable that can be converted to command signals that push the regulated variable farther from its set point. Feedforward information changes the set point in anticipation of an imbalance so that the regulated variable can remain stable as conditions change.
3. You would inject known volumes (V_1) of mannitol and Evans blue at known concentrations (C_1) into the blood of a subject. After a sufficient amount of time for the injected solutions to circulate around the body, you would take a blood sample and measure the concentrations of Evans blue or mannitol in the blood plasma (C_2). You can then use the formula given for calculating V_2 for mannitol, which will be the extracellular volume, and V_2 for Evans blue, which will be the blood plasma volume. Subtracting the blood plasma volume from the ECF volume will give the interstitial fluid volume.

RECAP 39.3

1. Fluctuations in body temperature can disrupt complex physiological processes because different steps or components of those processes are likely to have slightly different Q_{10} values. As a result, a temperature change can alter the integration of those steps or components.

2.

3. Isozymes can have different temperature optima, so expressing different isozymes that have temperature optima that match seasonal changes in the climate can result in seasonal acclimatization.

RECAP 39.4

1. In nature, the ectotherm can use behavioral adaptations such as basking and seeking shade to prevent significant changes in its body temperature. In the laboratory, it does not have the opportunity to bring those adaptations into play.
2. The animal gains heat from radiation, convection, or conduction if the environment is warmer than the surface temperature of the animal, and the animal loses heat if the environment is cooler than the surface temperature of the animal. Evaporation can only result in a loss of heat from the animal, and the magnitude of the loss depends on the amount of water that is evaporated on a heat exchange surface such as skin or respiratory passages.
3. In fishes, the blood leaving the heart goes to the gills, where it comes into temperature equilibrium with the surrounding water. In most fish, that blood flows down the center of the fish through a large vessel leading to lots of smaller vessels that perfuse the tissues of the fish, thus cooling those tissues. In “hot” fishes, the major blood flow from the gills is through peripheral vessels that give rise to smaller segmental vessels going into the muscle tissue. The vessels carrying blood in (arteries) run parallel and close to the vessels carrying blood out (veins). The veins carry heat produced in the muscle, but because of this countercurrent flow of blood in the arteries and veins, the heat from the venous blood warms the arterial blood flowing into the muscle, thus decreasing the loss of heat from the muscle tissue. Countercurrent heat exchange in “hot” fishes acts to keep the heat generated by the powerful swimming muscles in the muscle tissue.

RECAP 39.5

1. Within the thermoneutral zone, metabolism can remain at basal levels because the regulation of body temperature can be achieved by passive means such as changing blood flow to the skin and changing posture. However, as environmental temperature falls, a point will be reached when active thermoregulation is required, resulting in an increase in metabolism. This point is the lower critical temperature. Conversely, as the environment warms, a point will be reached when increasing blood flow to the skin and changing posture will not prevent a rise in core temperature, and active mechanisms such as sweating or panting are required, resulting in a rise in metabolism. This point is the upper critical temperature.
2. The segment of the metabolic rate curve in [Figure 39.16](#) that falls below the lower critical temperature (low end of the thermoneutral zone) represents the amount of heat production necessary to balance the amount of heat loss to the environment. That segment of the metabolic rate curve can be described by the equation shown. If there were no metabolic functions other than balancing heat loss, the heat loss and therefore the MR would be zero when $T_b - T_a$ equaled zero. Thus this MR line below the basal metabolic rate level projects to a T_a that is equal to T_b .
In the equation, the constant K stands for thermal conductance, which is the inverse of insulation. If the curve represented a desert versus a similar sized arctic animal, the curve would have a higher slope (K). The lower critical temperature would be higher for the desert versus the arctic species.
3. Heat is lost from the surface of the body, so a bigger, stockier animal will have a lower surface area-to-volume ratio than a smaller, slimmer animal. Thus, for closely related species, selection has favored larger, stockier variants in the colder latitudes.
4. Feedforward information serves to change set points in anticipation of an upcoming stressor. For example, exposure to a cold environment can elevate the set point for metabolic heat production, so that the increased heat loss from the body to the cold environment is balanced without requiring a drop in core

body temperature to trigger the response.

5. The mammalian thermostat is described as a proportional thermostat with an adjustable set point because the drive it generates to effector organs is proportional to the difference between hypothalamic temperature and a threshold hypothalamic temperature for activation of that response. The descriptor of adjustable set point refers to the role of feedforward information in altering the hypothalamic temperature thresholds for different thermoregulatory responses.

WORK WITH THE DATA, P. 832

1. Standardizing results to percent increases in treatments 1 and 2, averaging and calculating standard deviations for those two groups, comparing the two groups to determine if there is a possible order effect through use of a paired *t*-test.

	Percent increase, experiment 1	Percent increase, treatment 2
Subject	Control group (no cooling)	Treatment group (palmar cooling)
1	35.29	11.11
2	24.00	27.59
3	4.55	5.80
4	28.30	12.50
5	25.86	35.44
6	3.28	14.93
7	2.70	76.74
8	6.00	28.57
9	-5.26	28.95
	Treatment group	Control group
10	39.39	7.87
11	11.49	5.62
12	30.00	8.75
13	32.31	39.44
14	57.89	26.19
15	42.62	21.59
16	53.33	18.67
17	48.98	1.35
Mean	25.93	21.83
Standard deviation	18.80	17.53

The *P*-value (0.058) shows there is no significant difference between the two data sets and therefore there cannot be an order effect.

2. The standardized values (percent increases) are sorted according to treatment— palmar cooling or no cooling. Means and standard deviations are calculated and a paired *t*-test is applied to the data.

Subject	Palmar cooling	No cooling
1	11.11	35.29
2	27.59	24.00
3	5.80	4.55
4	12.50	28.30
5	35.44	25.86
6	14.93	3.28
7	76.74	2.70
8	28.57	6.00
9	28.95	-5.26
10	39.39	7.87
11	11.49	5.62
12	30.00	8.75
13	32.31	39.44
14	57.89	26.19
15	42.62	21.59
16	53.33	18.67
17	48.98	1.35
Mean	32.80	14.95
Standard deviation	18.54	12.88

The *P* value of < 0.008 is highly significant, indicating that the increases during the palmar cooling treatments were greater than the increases during the no cooling treatments.

3. The hypothesis that extracting excess heat from the body will increase the capacity of an individual's muscles to do work is supported by these data. Normalizing the data to percent increases and then

testing for order effects showed that there was no effect from whether the cooling or the control treatment came first. Testing for treatment effect, however, yielded a highly significant benefit to the cooling treatment.

FIGURE QUESTIONS

Figure 39.2 The muscles are connected to the bones and the bones are connected to each other by connective tissue. Bone is connective tissue, and without bones, the muscles would not be able to exert forces on the environment. Blood is also a connective tissue and supplies the muscles with oxygen and removes wastes and heat. Epithelial tissues line the blood vessels. Neural tissues carry the motor commands to control the contractions of the muscles.

Figure 39.8 The fall of the mouse's temperature at cold environmental temperatures and its rise at high environmental temperatures indicates the limitations on the mouse's ability to regulate its body temperature. At high environmental temperatures, the mouse's metabolic rate rises because active heat loss (e.g., sweating, panting, or licking) requires energy.

Figure 39.12 The fact that both Arctic and tropical mammals fall on this same curve means that BMR has not evolved as an adaptation to climate. If the BMR of arctic mammals was elevated to counter increased heat loss to the environment, the data points for arctic mammals should fall above the curve and the data points for tropical mammals should fall below the curve.

APPLY WHAT YOU'VE LEARNED

1. The group that reached a body temperature of 30°C in a significantly shorter time was the +2°C group. The starting temperature did have an effect on the rate of rewarming, which was 4.9°C/hr for the +2°C group and 3.8°C/hr for the -12°C group.
2. When an animal's body temperature is constant, there is a balance between heat entering the body and heat leaving the body.

$$\underbrace{\text{heat}_{\text{in}}}_{\text{metabolism} + R_{\text{abs}}} = \underbrace{\text{heat}_{\text{out}}}_{R_{\text{out}} + \text{convection} + \text{conduction} + \text{evaporation}}$$

Therefore for body temperature to rise, heat_{in} has to be greater than heat_{out} . For both groups of squirrels in this experiment, heat_{in} can only be coming from a single source, metabolism, since neither group has any source of radiant heat to absorb. However, the squirrels in the -12°C group encounter a much lower ambient temperature. Although they experience little conductive, convective, or evaporative heat loss when sequestered in a closed chamber, the -12°C group could experience greater radiative heat loss, which is a function of the difference between an animal's surface temperature and the ambient temperature. In addition, the -12°C group is starting the rewarming process at a lower T_b . Thus more metabolic heat must be generated by the -12°C group to reach a T_b of 30°C thus requiring a greater total metabolic output and a longer time.

3. The two primary generators of metabolic heat in mammals are shivering and non-shivering heat production. Shivering is the rapid cycling of contractions of antagonistic muscles that do no work on the environment, thus all of the energy released from ATP during this process is released as heat. Nonshivering heat production comes from brown fat. This tissue contains many mitochondria and a good blood supply (thus the brown color in comparison to white fat). The brown fat mitochondria contain a protein, thermogenin that uncouples the movement of protons from the production of ATP. Thus the fat substrate is metabolized, producing heat without producing ATP. These two mechanisms produce the heat to raise the body temperatures of the squirrels.

Chapter 40

RECAP 40.1

1. Epinephrine is a derivative of an amino acid, transported in solution in the blood, and acts on cell surface receptors to trigger an intracellular signaling cascade that produces an immediate response. Estrogen is a steroid hormone that is transported in the blood in combination with a protein carrier. Since it is lipid soluble, it diffuses into target cells to bind to an intracellular receptor that is then translocated to the nucleus and alters gene expression. Responses to the hormone are mediated through the products of that gene expression, all of which takes more time than the actions of epinephrine.
2. The presence of the same hormone in two species is not an indication of closeness of their evolutionary relationships because hormone structures are highly conserved even as their functions change. Therefore distantly related species can share the same hormones.

3. A single hormone can have different effects in the same species depending on the types of cells that express its receptors and also on the nature of the receptors themselves, which can activate different signal transduction pathways.

RECAP 40.2

1. During development, the posterior pituitary is derived from an outpocketing of the brain and the anterior pituitary is derived from an outpocketing of the embryonic mouth tissue. Thus the posterior pituitary is neural tissue, and it is nerve cells that produce and release the posterior pituitary hormones, which are neurohormones. The anterior pituitary comes from gut epithelium, and the secretory cells develop from gut epithelial cells.
2. Hypothalamic neurons release tiny quantities of releasing or release-inhibiting hormones that diffuse into portal blood vessels between the hypothalamus and the anterior pituitary. These hypothalamic hormones leave the portal capillaries in the anterior pituitary and diffuse to anterior pituitary cells that have receptors for those particular release or release-inhibiting hormones. Those anterior pituitary cells respond by changing the release of their hormones, which include four tropic hormones (thyrotropin, adrenocorticotropin, and the gonadotropins LH and FSH) and growth hormone.
3. Negative feedback in the hypothalamic control of endocrine function involves the inhibitory effect of the end hormone on the hypothalamic production of the hypothalamic releasing (or release-inhibiting) hormone that controls the anterior pituitary cells that produce the tropic hormones controlling the cells or gland that produce and release the end hormone.

RECAP 40.3

1. Decapitation of *Rhodnius* prevented molting when done 1 hour after feeding but not when done 1 week after feeding because of the time necessary for PTTH to be released and diffuse to the prothoracic gland in sufficient amounts to stimulate the release of ecdysone.
2. The female external phenotype is the default pathway in humans. That pathway is altered in normal XY individuals because of genes on the Y chromosome that stimulate the development of testes rather than ovaries. The testes produce the male steroid sex hormone that stimulates development of the male external phenotype. However, if an individual lacks receptors for the male steroid sex hormone, then it has no effect and the female phenotype develops.
3. In the prepubertal individual, sex steroids are produced in low amounts, but these low amounts provide sufficient negative feedback to the hypothalamus to inhibit the production of GnRH. As a result, the release of LH and FSH from the anterior pituitary is low. However, at the time of puberty, sensitivity of the hypothalamus to the circulating sex steroids is reduced, releasing the negative feedback control. Therefore production and release of GnRH as well as LH and FSH go up, stimulating the changes associated with puberty.

RECAP 40.4

1. A major cause of hypothyroidism is lack of iodine. Without adequate iodine, the thyroid cannot secrete active T3 and T4. As a result there is no negative feedback on the production of TRH and TSH. The elevated TSH causes increased production of thyroglobulin and growth of the thyroid gland. A major cause of hyperthyroidism is production of an antibody to the TSH receptor that binds to the receptor and keeps it activated. The result is continuous stimulation of thyroglobulin production. Even though the individual produces active T3 and T4, they cannot exert negative feedback on the hypothalamic-pituitary-thyroid system.
2. Vitamins are required in the diet because they are not produced in the body. Since vitamin D is produced in the body by the action of UV light on a precursor in the skin, converting it to calciferol, it is not a vitamin. Calciferol is converted to the active form calcitriol by enzymes in the liver and kidneys. Calcitriol (vitamin D) promotes the uptake of calcium from the gut and the kidneys, thereby raising blood calcium levels.
3. Insulin controls the rate of glucose uptake by cells by stimulating the cells to insert glucose transporters (passive transporters) into the cell membrane from a pool of those receptors in the cytoplasm. The glucose transporters in the cell membrane increase the permeability of the cell to glucose, which can then diffuse into the cell as long as its concentration in the extracellular fluid is high enough.
4. Stress stimulates the release of cortisol from the adrenal cortex. Cortisol helps the body deal with short-term stress by reducing cellular uptake of glucose, elevating blood pressure, inhibiting activity of the gut and the reproductive system, and even inhibiting the activity of the immune system. In the short run, these responses make more energy available to deal with the immediate stressor. Negative feedback from cortisol, acting through the hypothalamus and the pituitary gland normally shuts off the cortisol response to short-term stress. If, however, stress becomes chronic, as in a difficult job situation, cortisol levels remain high and the resulting higher blood pressure can lead to heart disease, the impaired immune system can lead to infections and diseases, the impaired digestion can lead to ulcers, and the

impaired glucose metabolism can lead to diabetes.

WORK WITH THE DATA, [P. 853](#)

1.

2. To determine if exercise increases BDNF levels in the hippocampus, you would assay BDNF levels in the hippocampus of the exercised and non-exercised mice, obtain average values and standard deviations, and do a *t*-test to determine the probability that the values for the two groups are the same. If P is < 0.05 , the values for the two groups are significantly different.
3. To determine if increased expression of FNDC5 in the hippocampus is sufficient to stimulate an increase in BDNF expression, you would culture some hippocampal cells in media that stimulates FNDC5 expression and some hippocampal cells in media that suppresses FNDC5 expression. You would then measure the levels of BDNF in those cultures. A *t*-test would reveal the probability that FNDC5 had no effect on BDNF expression. If those probabilities are < 0.05 , you would conclude that differences in FNDC5 expression are sufficient to influence BDNF expression.

WORK WITH THE DATA, [P. 862](#)

1. In the experiment in which irisin was injected into the mice kept on a high-fat diet, it was important to measure UCP1 expression as well as betatrophin because a relationship between irisin and UCP1 had been established earlier in exercise experiments. Therefore the measurement of UCP1 in that experiment was a positive control for activity of the injected irisin.
2. The mice were placed on a high-fat diet to model the condition of obesity and pre-diabetic insulin resistance.
3. The data support the hypothesis that irisin could reduce obesity and lower the risk for type II diabetes for the following reasons. Using *t*-tests confirms that the two groups of mice prior to irisin application did not differ in body mass. However, the irisin-treated mice showed a significant ($P < 0.05$) reduction in body mass, whereas the control mice showed no significant change in body mass. The irisin-treated mice had significantly lower fasting insulin levels and blood glucose levels than the control mice did, also indicating a lowered risk for type II diabetes.

FIGURE QUESTIONS

[Figure 40.7](#) These results suggest that cells in the hypothalamus are producing a MSH release inhibiting hormone.

[Figure 40.9](#) A mutation resulting in nonfunctional androgen receptors would result in XY individuals with female phenotype including external sex organs and secondary sexual characteristics.

APPLY WHAT YOU'VE LEARNED

1. The epinephrine in the irrigation fluid is affecting the dilator muscle fibers. When comparing the two types of surgeries, those that used the epinephrine-containing solution dilated the pupil past the 5-mm diameter and kept it dilated for a longer period of time than those surgeries that did not use the epinephrine-containing irrigation fluid. Since dilator muscle contractions are what cause the pupil to enlarge, these must be the muscle fibers affected by epinephrine.
2. Although both the constrictor muscle fibers and dilator muscle fibers are smooth muscle tissue, only the dilator muscle fibers contain a corresponding receptor protein on their cell surface that will bind to epinephrine. Thus the dilator fibers are target cells for epinephrine while the constrictor fibers are not. Once the epinephrine binds to the receptor protein on the dilator fibers, it begins a signaling cascade within the muscle fibers that promotes strong and prolonged contractions within the fibers. This produces the larger than 5-mm diameter pupil seen in the surgeries that used epinephrine-containing irrigation fluid.
3. Epinephrine affects the cardiovascular system by increasing the heart rate and blood pressure. It causes arterioles in the digestive system and skin to contract but causes the arterioles in the skeletal muscles to

dilate. It causes the liver to break down glycogen into glucose and stimulates adipose tissue to break down fat into fatty acids. These different effects are stimulated by the same hormone binding to receptors on the surface of each type of cell. The reason the responses are so varied is because of what happens inside each cell type after the receptor has been activated. Each cell will have a different signaling cascade that results in different intracellular processes. The difference in processes is determined by the type of cell (cardiac muscle vs. smooth muscle vs. hepatocytes vs. adipocytes, etc.) and by the types of intracellular signaling molecules that are created.

4. To elicit a pupillary dilation from the constrictor fibers, these muscle fibers must relax beyond their normal resting state. This is the effect of atropine. Since atropine inhibits the interaction of acetylcholine with its receptor, this must mean that acetylcholine is the neurotransmitter that stimulates constrictor fibers to contract and reduce the pupil size. It also means that there is normally a baseline level of acetylcholine that keeps the constrictor fibers somewhat contracted. Thus the autonomic nervous system controls pupil diameter by releasing both epinephrine and acetylcholine—epinephrine to cause dilator fibers to contract and enlarge the pupil, and acetylcholine to cause constrictor fibers to contract and decrease the pupil size.

Chapter 41

RECAP 41.1

1. Innate immunity is nonspecific, acts rapidly, and recognizes broad classes of molecules. Adaptive immunity is specific, acts more slowly, and is longer lasting.
2. The TLR pathway is involved in innate immunity to bacterial infections. Bacteria have molecules that act as pathogen-associated molecular patterns (PAMPs), and these normally activate the TLR pathway which results in white blood cells producing cytokines and other defensive molecules. If this does not occur, people will be especially susceptible to bacterial infections.
3. The genomes of both the insect and the human would have genes for innate immunity, such as barriers and the TLR pathway, but only the human would have genes for adaptive immunity: antibodies, T cell receptors, and T and B cells.

RECAP 41.2

1. The physical barrier of skin prevents infection. Mucus traps and removes bacteria so they cannot infect. Lysozyme hydrolyzes bacterial cell walls. Defensins insert into the bacterial cell membranes, rendering them leaky. Once below the skin, the bacteria come in contact with complement proteins, which provoke phagocytosis, and phagocytes that ingest and destroy the bacteria.
2. The bacterium has an arrangement of atoms on its molecules called PAMPs. These are recognized by receptors on the human body cells, and they initiate a response. Dust particles lack PAMPs.
3. The splinter initiates the inflammatory response. See [Figure 41.5](#).

RECAP 41.3

1. Humoral immune response: Free virus binds to B cells already making antibodies that react with viral antigens (recognition). These B cells are selected to divide and form a clone. The clone produces more antibodies against the virus. These antibodies bind to free virus in the bloodstream, and phagocytes ingest and hydrolyze the virus-antibody complexes.
Cellular immune response: Virus infects cells in the respiratory tract. Some of these cells break down the viral proteins and present fragments on their surfaces (antigen presentation). T cells with a T cell receptor that can bind to the viral fragment bind to the antigen-presenting cells. These T cells stimulate the formation of cytotoxic T cells that can then kill the virus-infected cells.
2. The older people had memory cells that could make antibodies to bind to the 1918 flu strain. Since the 1918 flu strain was similar to the 2009 virus, these people were able to mount a strong immune response to the 2009 virus.
3. Vaccines are inactive antigens that still provoke an immune response. Vaccination promotes a proliferation of clones that produce antibodies (B cells) or T cell receptors (T cells) that bind to the injected viral antigen. Some memory cells remain. These will be needed to mount a massive immune response when the virus (with antigen) infects later.

RECAP 41.4

1. See [Figure 41.8](#). The antigen-binding site of an antibody has heavy and light chains in a unique three-dimensional configuration that binds a particular antigenic determinant. This is similar to an enzyme active site that binds a substrate. In both cases, binding is noncovalent. A major difference is in the result of binding: an antigen does not change its covalent structure when it binds to an antibody, whereas a substrate does change covalently when it binds to an active site.
2. Both immunoglobulins and T cell receptors have constant and variable protein regions, bind antigens,

and have great variability in primary structure. T cell receptors are membrane proteins of T cells. Immunoglobulins can be either membrane proteins of B cells or secreted proteins in the blood.

3. There are thousands of different enzymes in an individual but potentially millions of different specific antibodies. Every cell in an animal has the genetic information for all enzymes. Each immunoglobulin, however, is derived from a unique gene (produced by DNA rearrangements) in a B cell or a clone.

RECAP 41.5

1. By inhibiting T cell development, cyclosporine blocks TH cell binding to transplanted cells. This stops cellular immunity from occurring, because TH cell binding releases cytokines to attract TC cells that would kill the transplanted cells.
2. Inside the infected cell, the virus is broken down into fragments, and some peptide fragments are displayed on the cell surface along with MHC protein (class I). A cytotoxic T cell displaying a T cell receptor that is specific for the peptide on the target cell binds to the target cell and initiates the cellular immune response.
3. Increased Treg activity would inhibit the cellular immune response, so the tumor would evade the adaptive immune system.

RECAP 41.6

1. An antigen in peanuts binds to a B cell displaying an anti-peanut protein antibody. This causes production of a clone of plasma cells that initially make IgG and then switch to IgE. The IgE binds to mast cells, which release histamine, causing symptoms of distress.
2. Desensitization involves giving the person a small amount of peanut protein that provokes IgG synthesis but not IgE, so mast cells are not stimulated.
3. The anti-CTLA4 treatment for cancer removes inhibition of the T cell cytotoxic re-sponse to self antigens. This causes T cells to bind to and kill cancer cells. A side effect might be generalized autoimmunity.
4. Experiments might involve testing vaccinated people for neutralizing antibodies against HIV (humoral immunity) and looking for T cell activity against HIV-infected cells (cellular immunity).

WORK WITH THE DATA, P 878

1. While some people had low titers and other had high titers of anti-Russian flu antibodies, the general trend over time was for the titers to increase. As these people were exposed to the typical flu strains year after year, their anti-flu virus responses, including to the Russian flu, increased. This indicates that there were some general antibodies that bind to all flu strains.
2. There was little change in the antibody titers to CMV. Note that the y axis is much lower quantitatively in this case than the y axis for anti-flu titers. CMV has epitopes unrelated to the flu virus, so anti-CMV antibodies will not be made when a person is exposed to flu. The data indicate that the increase in flu virus strain immunity was flu virus-specific.
3. The antibodies that developed were mostly broadly reactive. These antibodies could be used to develop a vaccine that might work on old as well as new strains of flu virus.

FIGURE QUESTIONS

Figure 41.5 Antihistamines block mast cells from making histamine. Blood vessels at a site of injury do not dilate or become leaky, so phagocytes are not attracted to the site and fluid does not enter the damaged tissue. In other words, inflammation does not occur in response to bacterial infection.

Figure 41.6 A reduction in T_H cells negatively affects both adaptive cellular and humoral immunity. With fewer T_H cells, immune response to an HIV infection is weak, both in terms of antibodies generated against the virus and cellular immune responses generated against virus-infected cells.

Figure 41.7 Small numbers of previously unexposed B cells are constantly differentiating to make antibody against Ebola and any other possible antigen. If there is no Ebola infection, these cells do not form clones in clonal selection and die off. But other previously unexposed B cells making anti-Ebola antibodies take their place.

APPLY WHAT YOU'VE LEARNED

1. By 3 weeks after the initial treatment, ADA and deoxyadenosine levels were normal. Weekly injections were probably needed because ADA gets broken down in blood serum.
2. Matched sibling and matched family donors had almost the same survival percentage: 87% and 88%, respectively. Matched unrelated donors were not nearly as successful, with only 67% survival. However, even this was better than the mismatched family donors, which had only 43% survival. The lowest survival of all was shown by mismatched unrelated donors: 29%. The survivorship of untreated patients might be similar to that with mismatched unrelated donors, but perhaps with even lower survival.
3. In gene therapy, hematopoietic stem cells are the cells that receive the genetic modification. Thus they are the only cells that will be able to produce and maintain normal levels of ADA. However, all cells produce ADA, because all cells undergo a certain level of DNA metabolism. ERT could keep other body

cells from reaching dangerously high levels of deoxyadenosine.

Chapter 42

RECAP 42.1

1. Budding and regeneration begin with somatic (body) cells of the parent, whereas parthenogenesis begins with a germ (sex) cell, an egg that is not fertilized.
2. Global climate change is more likely to have a negative impact on asexually reproducing species, because they have less genetic variability to facilitate the evolution of adaptive changes that meet the new challenges imposed by climate change.
3. Flora must have reproduced through parthenogenesis, an ability that would be adaptive for an island-dwelling species should a weather event eliminate all potential mates or cause a female to be relocated to another island with no potential mate. If the offspring of a parthenogenic reproductive event are male, they would be able to mate with their mother to initiate a new population of sexually reproducing individuals.

RECAP 42.2

1. Human oocytes remain in prophase of the first meiotic division much longer than spermatocytes, and therefore the opportunity for crossing over is much greater.
2. Without cytoplasmic bridges between the spermatids of mammals, all of the spermatids would not receive gene products of the X chromosome that seem to be necessary for sperm survival. Thus all surviving sperm would lack a Y chromosome, and the offspring of that individual would all be female.
3. The egg is covered by protective layers that prevent sperm from contacting the egg cell membrane. The egg emits species-specific chemical attractants that stimulate sperm of its species to swim toward the egg. The protective coat of the egg also contains species-specific signals that stimulate the acrosomal reaction of the sperm, releasing enzymes that digest a path through the protective coat. The sperm head is coated with molecules (bindin) that have receptors on the inner protective coat of the egg, and when those molecules bind their receptors, the sperm contacts and fuses with the egg cell membrane. That event stimulates the blocks to polyspermy (fast and slow) that prevent additional sperm from fusing with the egg cell membrane.
- 4a. The possibility of finding a mate is low.
 - b. Sequential hermaphroditism would be advantageous to avoid inbreeding in a species that produces large numbers of offspring that remain in the same area.
 - c. Sequential hermaphroditism would also be advantageous in a population where single dominant females control essential resources such as territory. Male offspring in that population would have the chance to reproduce, but females would not until the dominant female was removed. At that time a male could transition to female and take the place of the single dominant female in the group.

RECAP 42.3

1. Semen contains fibrinogen secreted by the seminal vesicles. The prostate secretes a clotting enzyme that causes the fibrinogen to polymerize and form a clot. The prostate also secretes the enzyme fibrinolysin, which eventually breaks down the clot and liberates the sperm.
2. Sertoli cells nurture and promote the maturation of sperm, beginning with the primary spermatocyte stage. They provide a suitable environment and essential nutrients. Tight junctions between Sertoli cells protect the developing sperm from water-soluble toxic substances that might be circulating in the blood.
3. Sexual stimulation of the male causes nerve endings in the penis to release a neurotransmitter that stimulates endothelial cells in the blood vessels to release NO. NO diffuses into the muscle cells controlling the diameter of the penile arteries, causing them to relax through increased production of cGMP. The resulting increase in blood flow in those arteries compresses the veins carrying blood out of the penis, and it becomes engorged with blood (an erection). A phosphodiesterase breaks down cGMP, so a phosphodiesterase inhibitor prolongs the effects of cGMP production.
4. Since prepubertal testes are responsive to LH and FSH, the cause of their inactivity must either be low production and release of LH and FSH by pituitary gonadotropes or low production of GnRH by the hypothalamus.

RECAP 42.4

1. The events in the ovary that are responsible for the onset of menses are the degradation of the corpus luteum and the consequent decrease in production and release of estrogen and progesterone. However, if a blastocyst implants in the uterus, it produces human chorionic gonadotropin (hCG), which maintains the corpus luteum until the extraembryonic membranes take over the production of estrogen and progesterone.
2. The granulosa cells nurture the developing egg, providing it with nutrients, growth factors, and mRNAs.

The granulosa cells also produce estrogen and progesterone in response to FSH. Estrogen is produced by the granulosa cells from testosterone that is produced in the outer cells of the follicle, the thecal cells. Estrogen stimulates the granulosa cells to produce FSH receptors, but at the same time estrogen exerts negative feedback on the production and release of FSH from the anterior pituitary. Since multiple follicles begin to mature in each menstrual cycle, only the one with the most FSH receptors fully matures as the estrogen levels rise and FSH levels fall.

3. Prior to the onset of labor, the contractility of the uterine muscle increases, and at the same time the growing fetus is causing more stretch of the uterine muscle. Stretch of the uterine muscle stimulates contractions, pressing the head of the fetus onto the cervix. That stimulates neural signals to the hypothalamus, causing it to release oxytocin from the posterior pituitary. Oxytocin increases the uterine contractions, which in turn puts more pressure on the cervix, resulting in even more oxytocin being released from the posterior pituitary—a positive feedback loop

RECAP 42.5

1. The condom is the only contraceptive technology that can protect against STDs because if used properly it protects each partner from contact with the body fluids of the other
2. The pill delivers a high dose of progesterone that exerts negative feedback on the hypothalamic-pituitary axis to inhibit the production and release of LH and FSH, which are essential for the maturation and release of an egg from the ovary. RU-486 is an antiprogesterone drug. During the luteal stage of the menstrual cycle, high levels of progesterone from the corpus luteum maintain the endometrium of the uterus in a receptive condition to receive a blastocyst. Blocking that action of progesterone can prevent implantation of the blastocyst or promote sloughing of the endometrium.
3. IVF can be used to prevent transmission of a genetic disease because cells can be taken from the early embryo in culture and analyzed for the suspected defective gene. Only embryos that do not carry the defective gene can then be selected for implantation into the uterus of the mother.

WORK WITH THE DATA, [P. 909](#)

1.

The data for this group were mixed, with minor peaks in mean PRL for the group occurring on days 7 and 10, indicating that some of the wallabies had broken diapause over that period of time. These rises occurred later than measured in the saline-treated (control) wallabies, but sooner than in the daily-treated wallabies. Thus the 48-hr PRL treatments were marginally effective in preventing the breaking of diapause.

FIGURE QUESTIONS

Figure 42.3 The selective advantage that could accrue to a bisexual species that becomes unisexual is that each member of the population could produce offspring. A disadvantage would be loss of genetic diversity.

Figure 42.6 If two sperm fertilized an egg, there would be two sets of male chromosomes in the egg, which would disrupt the subsequent cell divisions.

Figure 42.9 An enlarged prostate gland could squeeze the urethra shut and prevent or impair urination.

Figure 42.13 Hormonal contraceptive pills simulate the second half of the ovarian cycle, the luteal phase when estrogen and progesterone levels are high. These two hormones exert negative feedback that inhibits the release of gonadotropin, LH, and FSH which are essential for maturation of the egg and ovulation.

APPLY WHAT YOU'VE LEARNED

1. Following the mating behavior between the male and group A female koalas, the female koala's pituitary gland released a surge of LH into the bloodstream. This surge in LH stimulated ovulation. An egg was fertilized by the male's sperm, beginning a period of pregnancy that lasted about 35 days. No LH increases or pregnancies occurred in the Group B females. This experiment eliminates the possibility that

- the signal for ovulation could be a stimulus, such as a pheromone, from close proximity to a male koala.
2. The results from groups A and C show that neither artificial insemination procedures without semen nor tactile stimulation of the urogenital sinus stimulate LH surges or ovulation. However, AI with semen or artificial stimulation followed by semen injection both result in LH surges and ovulation. These results lead to the hypothesis that some component of the male semen is both the necessary and sufficient stimulus for the LH surge and subsequent ovulation. Clearly tactile stimulation alone or injection of a liquid volume into the urogenital sinus did not induce ovulation.
 3. A possible selective advantage of reflex ovulation is that the female can choose the optimal time and the optimal mate for reproduction. If she has mature eggs available to ovulate, but she is not sexually receptive unless environmental conditions are good and a potential mate is at hand, reflex ovulation can optimize her chances of reproductive success.

Chapter 43

RECAP 43.1

1. The sperm contributes the centriole to the embryo, and the centriole is the origin of the microtubules of the primary cilia, which serve signaling functions.
2. The unfertilized frog egg has an animal (upper) and a vegetal (lower) hemisphere. The outer cytoplasm of the animal hemisphere is pigmented, but the vegetal hemisphere cytoplasm is not. The sperm binds to the animal hemisphere and stimulates rotation of the outer (cortical) cytoplasm toward the site of sperm entry. This rotation creates a band of more lightly pigmented cytoplasm opposite the site of sperm entry.
3. In the unfertilized frog egg, β -catenin and its degrading enzyme GSK-3 are homogeneously distributed. With sperm entry and cortical rearrangement, vesicles containing a GSK-inhibiting protein are translocated from the vegetal pole to the site opposite sperm entry. That protein regionally prevents the degradation of β -catenin on the dorsal side of the blastula.

RECAP 43.2

1. Complete cleavage occurs in eggs that have little yolk. In these eggs the early cleavage furrows can divide the egg completely. In eggs with a lot of yolk, the cleavage furrows cannot penetrate completely and the blastula forms as a disc of cells that sits on top of the yolk mass.
2. Cleavage in mammals is very slow, allowing enough time for gene expression to occur. In sea urchins and frogs, cleavage occurs very rapidly, precluding gene expression between cell divisions.
3. Mammals have regulative development, meaning that each cell of the blastula is not irreversibly determined, so if the blastula is divided in half, identical twins can develop. Since development is mosaic in most invertebrates, if the blastula is divided, each part will be lacking certain elements and will not be able to complete development.
4. Germ cells are determined at the time of early cell divisions of the embryo that take place during formation of the blastula. These presumptive germ cells will not differentiate until the gonads develop and they migrate into those gonads. The origin of skin cells is ectoderm that is determined during a later developmental stage—the gastrula—and these ectodermal cells differentiate rapidly to form the skin of the embryo.

RECAP 43.3

1. Gastrulation in both the sea urchin and the frog proceeds with an involution forming a blastopore. In the sea urchin, the cells involuting are similarly determined, but in the frog, tissue interactions differ according to location around the blastopore, and the involuting cells become differentially determined.
2. The criterion of necessity means that a component of a process must be present for that process to occur. Spemann's experiment, constricting the fertilized egg so that the gray crescent was only in one daughter cell or in both daughter cells, showed that the gray crescent was necessary for embryo development. The criterion of sufficiency means that a component of a process can alone cause the process to occur. In the Spemann-Mangold experiments, sufficiency was demonstrated by showing that when the dorsal lip of the blastopore was transplanted to another location on the blastula, it stimulated another axis of development.
3. The first involuting cells of the primary organizer express the transcription factor Goosecoid, and as those cells move anteriorly, Goosecoid suppresses the expression of certain transcription factors in neighboring tissues that have to be suppressed so that organs appropriate for the head region can develop. Cells that leave the dorsal lip of the blastopore later express different transcription factors that also have suppressive action on expression of other transcription factors in neighboring tissues, enabling the induction of region-appropriate organs.
4. Gastrulation in reptiles and amphibians differs because the blastula of amphibians is a sphere, but the equivalent stage of reptilian development is a flat sheet of cells, the blastodisc. In amphibians, the cell

movements of gastrulation take place through a hole in the blastula (blastopore), while in reptilian blastodiscs, a longitudinal slit (primitive streak) forms and the cell movements of gastrulation take place through that slit. In amphibians, the ingress of cells through the blastopore creates the archenteron (primitive gut). No archenteron forms in the reptilian embryo, but the endodermal and mesodermal cells that pass through the primitive streak migrate forward to become gut and other structures.

RECAP 43.4

1. The ectoderm over the notochord thickens on either side of the midline to form ridges aligned on an anterior-posterior axis. These ridges grow until they meet on the midline, forming the neural tube. The most lateral cells of these ridges break free to form neural crest cells, while still more lateral ectoderm comes together and merges to cover the neural tube.
2. A somite is a segmental and bilateral block of mesodermal cells that gives rise to vertebrae, ribs, trunk muscles, and limbs.
3. Vertebrates have groups of Hox genes arranged in linear order on multiple chromosomes. These genes are expressed along the anterior-posterior axis in the same sequence as they occur on the chromosomes. As a result, each anterior-posterior region of the embryo receives different combinations of Hox gene products in different amounts, producing a large combinatorial mix of signaling molecules.

RECAP 43.5

1. The yolk sac and allantois grow out from the hypoblast and consist of endoderm and mesoderm. The chorion and amnion develop from ectoderm and mesoderm.
2. The blastocyst divides into a trophoblast group and a hypoblast group of cells. The trophoblast interacts with the uterine lining to embed the embryo into the endometrium and to send out projections to make contact with maternal blood vessels. Cells of the hypoblast grow out to form what in birds would be the yolk sac, but there is no yolk. These hypoblast cells and the trophoblast cells form the placenta.
3. The first trimester is a time of great sensitivity of the embryo to environmental risks because this is the time when many signaling cascades are setting up subsequent processes of determination, differentiation, and development. Therefore the earlier any necessary lifestyle or environmental changes are made, the better.

WORK WITH THE DATA, [P. 929](#)

1.

2. The experiment did not include left flow because we know left flow is the normal stimulus and that it is only disrupted by a fast right flow. This experiment was aimed at determining the sensitive period for the ability of that disruptive stimulus to alter the normal developmental pattern.
3. The data from embryos of different developmental stages support the conclusion that there is a sensitive phase of development where the left-right symmetry of the embryo is determined, and that it is between the presomite and 1-somite stages.
4. The results on 1-, 2-, and 3-somite wild-type embryos exposed to fast right flow show that the left-right asymmetry was determined at an earlier stage and that the embryo is no longer sensitive to direction of flow over the node.

FIGURE QUESTIONS

Figure 43.7 Gastrulation involves the involution of vegetal pole cells over the lip of the blastopore to form the archenteron thus forming the lining of the gut.

Figure 43.8 Epiboly spreads the animal pole cells over the entire embryo and results in the formation of ectoderm, the cells that form the skin and structures associated with the skin.

Figure 43.13 Hormonal contraceptive pills simulate the second half of the ovarian cycle, the luteal phase when estrogen and progesterone levels are high. These two hormones exert negative feedback that inhibits the release of gonadotropin, LH, and FSH which are essential for maturation of the egg and ovulation.

APPLY WHAT YOU'VE LEARNED

1. No, the symptoms are not consistent with vitamin A deficiency. The baby's defects are in mesenchyme tissues. A deficiency of vitamin A would most likely lead to defects of tissues derived from the ectoderm. In fact, the defects exhibited are consistent with an excess of vitamin A.
2. The ectoderm and the mesoderm express different genes. This results in mesoderm-derived cells being sensitive to excesses of vitamin A and ectoderm-derived cells being sensitive to too little vitamin A.
3. Individuals with this variant may be expected to be less susceptible to valproic acid. Because the variant enhances progression through G1 phase, the effect of valproic acid impeding this progression should be mitigated.
4. Even for women who have not been exposed to valproic acid, supplements of folic acid have been shown to reduce the frequency of neural tube defects. Given that valproic acid exposure increases risk for these defects, additional supplements of folic acid may counteract the effect of valproic acid. The extent to which additional folic acid could help would depend in part on whether and how these chemicals are involved in the same developmental processes. Valproic acid may have effects early in pregnancy—perhaps even before the woman knows she is pregnant—because neural tube formation is affected by processes that occur early in pregnancy.
5. Because deficiencies of folic acid increase the risk of neural tube defects, the efficiency of the receptor should affect this risk. Individuals who have receptor proteins that are more efficient in bringing folic acid to the cell should have greater cellular availability of folic acid and thus be at lower risk for neural tube defects compared with individuals who have less efficient receptor proteins.

Chapter 44

RECAP 44.1

- 1a. Refer to [Figure 44.1](#).
- b. At a chemical synapse, a chemical signal crosses the synaptic space between neurons. A neurotransmitter released by the presynaptic nerve endings diffuses across the synaptic space to bind to receptors on the postsynaptic membrane.
2. A neuron can receive both excitatory and inhibitory input at multiple synapses located throughout its dendrites and on the cell body. Summation of inputs determines whether the postsynaptic neuron becomes sufficiently depolarized to initiate an action potential.
3. Astrocytes can take up neurotransmitters that have been released into the synapse and thereby control the postsynaptic response. Astrocytes can also directly release neurotransmitters that bind to receptors to affect the excitability of a neuron.

RECAP 44.2

1. The Nernst equation calculates the membrane potential that will exist across a membrane due to the movement of a specific ion across that membrane, given the concentration difference of that ion on the two sides of the membrane. The dominant ion responsible for the membrane resting potential is K^+ , but the potential calculated from the K^+ concentrations by the Nernst equation does not equal the measured membrane potential. This is because the membrane is also slightly permeable to other ions, and they contribute to the measured membrane potential. The Goldman equation predicts membrane potential more accurately because it takes into account all ions that have concentration differences across the membrane as well as the relative permeability of the membrane to those ions.
2. Inhibitory inputs to the dendrites of a neuron cause hyperpolarization of the dendrite membrane, and excitatory inputs cause depolarization. These changes in membrane potential spread to the neuron's cell body. The resulting membrane potential of the cell body is a graded membrane potential because it is always reflecting the sum of the dendritic inputs. That graded membrane potential spreads to the base of the axon, which fires action potentials if its membrane potential reaches threshold for its electrically gated Na^+ channels. Therefore the rate of action potential generation is a function of the graded membrane potential of the neuron's cell body, hence an integration of all of the dendritic inputs.
3. When the voltage-gated Na^+ channels open in a patch of membrane, that patch depolarizes. That local depolarization spreads by electrical conduction to neighboring regions of membrane, bringing them to threshold and thereby causing their electrically gated Na^+ channels to open and regenerating that action potential. This process continues down the length of the axon.
4. If the axons of the motor neurons that stimulate the muscle are demyelinated, the conduction velocity will be decreased and reflected in a longer delay for the muscle to respond to the electrical stimulation.

RECAP 44.3

1. The motor end plate contains chemically gated Na^+ channels and voltage-gated Na^+ channels. The chemically gated channels respond to the neurotransmitter acetylcholine to depolarize the motor end

plate. The voltage-gated channels respond to that local depolarization by generating action potentials that spread to the adjacent muscle cell membrane.

2. The action of a neurotransmitter depends on the receptor types in the postsynaptic membrane, and they can initiate excitatory or inhibitory responses in the postsynaptic neuron.
3. Asphyxiation is the inability to breathe. Breathing requires regular activity in the motor neurons controlling the respiratory muscles. The inhibition of acetylcholinesterase by sarin results in the accumulation of acetylcholine in the synapses between the respiratory motor neurons and the respiratory muscles, reducing the ability of those muscles to relax between breaths.
4. Electrical synapses are fast but do not integrate information well. Electrical synaptic input does not allow temporal summation of inputs, as electrical synapses require a large area of contact between pre- and postsynaptic cells for effective transmission thus limiting the numbers of synapses that can be formed between two neurons. Finally, electrical synapses cannot provide inhibitory input.

RECAP 44.4

1. Ganglia are collections of nerve cell bodies. They tend to be concentrated in the anterior region of many invertebrates because that is where large numbers of sense organs are located.
2. See [Figure 44.14](#).
3. In the knee-jerk reflex the same stimulus can cause contraction of a muscle through an excitatory synapse and relaxation of the antagonist muscle because of an inhibitory interneuron.
4. The part of the vertebrate brain that increases the most in going from fish to reptiles to mammals is the most anterior part of the brain, the cerebrum.

WORK WITH THE DATA, P. 945

1. Plugging the values in the table into the equation gives:

Substituting $2.3RT/F \log$ for $RT/F \ln$:

Assuming T = room temperature, $2.3RT/F = 58$ (see [Figure 44.5](#)).

So,

$$V_m = 58 \log 0.1118$$

$$V_m = -55.2 \text{ mV}$$

If you use the Nernst equation:

$$\text{K}^+: E_K = 58 \log (5/140) = -84 \text{ mV}$$

$$\text{Na}^+: E_{\text{Na}} = 58 \log (145/10) = +67 \text{ mV}$$

$$\text{Cl}^-: E_{\text{Cl}} = 58 \log (110/20) = +43 \text{ mV}$$

Clearly the membrane potential is not due to K^+ alone. The membrane permeabilities to Na^+ and to Cl^- have a slight depolarizing influence on the resting potential of the mammalian neuron.

WORK WITH THE DATA, P. 954

1. During the dark phase the WT mice had significant discrimination scores during testing, indicating that they learned to recognize the training object. The DS mice did not have significant discrimination scores and thus did not learn. These were the same results as obtained during the light phase.
2. When the experiment was done during the dark phase, the results for the saline-treated mice showed the same results as during the light phase—the WT animals learned to recognize the training object, and the DS mice did not. The results for the drug-treated mice, however, were different than they were in the light-phase experiment. PTZ treatment during the dark phase did not result in an improved ability of the DS animals to learn to recognize the training object. Thus the conclusion is that the drug has to be given during the light phase to have an effect.

FIGURE QUESTIONS

[Figure 44.2](#) The Purkinje cell has the most dendrites and therefore is likely to receive more inputs than the pyramidal cell, and certainly more than the retinal cell.

[Figure 44.11](#) You would expect either Cl^- channels or K^+ channels to be on the postsynaptic membrane.

[Figure 44.15](#) The pig has a proportionally larger olfactory bulb than the human—the other mammal in this comparison—so its olfactory sensory sensitivity is especially well developed.

APPLY WHAT YOU'VE LEARNED

1. The 1-second light stimulation of the hypocretin neurons caused depolarization of their membrane potentials and a large increase in the rate at which they fired action potentials. These results support the concept that ChR2 is a Na^+ channel and that light increases the Na^+ permeability of that channel, depolarizing the membrane and bringing the membrane potential to above the threshold potential for firing of APs.

2. The fact that the firing of the neurons followed precisely the trains of very short bursts of light (15 ms) indicates that the APs of the neurons were direct responses to the light.
3. The light stimulation of hypocretinergic neurons expressing ChR2 in sleeping mice shortened the latency to awakening. The same light stimulation had no effect on the mice not expressing ChR2. Above a frequency of 1 flash per second, the awakening response was not altered by the frequency of stimulation.
4. The fact that a blocker of the hypocretin receptor eliminated the awakening effect of the light stimulation supports the conclusion that the effect was mediated by the release of hypocretin by the stimulated neurons.

Chapter 45

RECAP 45.1

1. Mechanical stimulation of the stretch receptor dendrites by stretch of the muscle they innervate causes graded depolarization of the stretch receptor neuron cell body—the receptor potential. The receptor potential spreads to the axon hillock, and if it depolarizes the membrane of the axon hillock to threshold, a Na^+ action potential is fired in the axon.
2. The interpretation of an action potential depends on its target neuron in the brain. If the action potential arrives in a nerve of the optic tract projecting to the visual cortex, it is interpreted as light, but if a similar action potential arrives in an olfactory nerve projecting to the olfactory bulb, it is interpreted as smell.
3. The molecules responsible for the distinctive flavor of peppers are received through chemoreceptors that activate a G-protein signaling cascade that open cation channels in the receptor membrane. Capsaicin, however, directly activates a TRP protein that also serves as a thermosensor, and that protein itself is a cation channel that opens when activated by its specific stimuli.
4. Adaptation is the property of a sensory system to stop responding to a constant level of receptor stimulation. Adaptation is important when it is of value to recognize when stimulation changes but it is not necessary to have continuous information. An example is the activation of skin tactile sensors by your clothing. Adaptation would not be advantageous when the information is critical, such as pain sensations, or when constant levels of information are essential, such as from the sensory neurons that signal postural muscle tone.

RECAP 45.2

1. The odorant receptor neurons (ORNs) that share the same receptors project to the same glomerular cells in the olfactory bulb. Thus the identification of a particular odorant depends on the pattern of connectivity of the ORNs that are activated.
2. An olfactory system signals intensity of a stimulus—whiff versus repulsive odor—by the frequency of action potentials it generates. The discrimination between a skunk and a skunk cabbage depends on the mixture of odorant molecules.
3. For salt, extracellular fluids including saliva have a high concentration of NaCl , therefore a lower sensitivity is appropriate for sensing concentrations above that constitutive level. For sweet, the selective pressure for its evolution was the ability to discriminate between high and low energy foods. A low sensitivity motivates the selection of higher energy foods. Bitter is a characteristic of many protective, hence poisonous, compounds that evolved in plants to discourage predation, so a high sensitivity helps avoid poisoning.
4. With only five classes of taste receptors we can sense a great variety of tastes because (1) some classes have multiple receptor genes; (2) a substance may trigger multiple receptor classes and therefore create a mixed signal; and (3) information from taste receptors is integrated with information from olfactory receptors as well as thermoreceptors (TRP channels) and tactile receptors.

RECAP 45.3

1. Different mechanosensor cell types enable responses to different aspects of touch such as sharpness, texture, pressure, vibration, and itch. Different rates of adaptation of touch receptors make it possible to discriminate between stimuli that are relevant and those that aren't. Slowly adapting mechanosensors such as those in postural muscles provide continuous information. Rapidly adapting mechanosensors provide information about changing conditions and also improve spatial and temporal sensory ability.
2. The activity of a muscle spindle stretch receptor increases the activity in the motor neuron to that muscle. The functional significance of this property of muscle spindle stretch receptors is that it enables continuous adjustments to changes in load, such as when you are holding a glass that is being filled. The activity in the Golgi tendon organ inhibits the activity in the muscle creating the stretch of that Golgi tendon organ. The functional significance is the prevention of damage to the muscle and tendons through the generation of too much tension, such as when you are attempting to pick up objects that are too heavy.

3. Different frequencies of sound pressure waves cause different frequencies of flexion of the tympanic membrane, and these movements are transmitted and amplified by the ossicles of the middle ear into vibrations of the oval window membrane of the fluid-filled inner ear. Those vibrations create pressure waves in the fluid of the inner ear. That fluid surrounds the basilar membrane in the vestibular and tympanic canals. The membrane grades from thick at the proximal end of the canal to thin at the distal end. Pressure waves of different frequencies in the fluid of the tympanic canal cause the basilar membrane to vibrate in different locations. The hair cells are on the basilar membrane, and therefore different sets of hair cells are activated by pressure waves of different frequencies.

RECAP 45.4

1. Ommatidia are excellent at detecting movement as moving objects in a visual field switch neighboring ommatidia “on” and “off.” However, since each ommatidium is receiving light from only a small but discrete portion of the total visual field, only a pixilated (low-resolution) image can be formed.
2. When photons excite rhodopsin, its conformation changes and that activates a G protein that activates a phosphodiesterase that converts cGMP to GMP. The decrease in cGMP levels causes the cGMP gated Na^+ channels to close, reducing the dark current. Na^+ is also pumped out of the proximal end of the photoreceptor cell and its membrane potential hyperpolarizes.
3. Rods and the various cones have different spectral sensitivities because they have slightly different opsins. The structure of the opsin determines which wavelengths of light a cell will absorb and how it will activate its associated 11-cis-retinal.
4. You cannot discriminate color in the periphery of your visual field because the cone cells are concentrated in the fovea, which receives light only from the center of the visual field. Rods do not distinguish color and are more abundant in the peripheral retina.
5. Two reasons why vision is impaired when you come from a brightly to a dimly lit environment are that bright light bleaches many rhodopsin molecules, and the amacrine cells have to readjust the range of brightness sensitivity of the retina.

WORK WITH THE DATA, P. 963

1. The expression of TRPA1 in the python is much greater in the TG than in the DRGs. In contrast, the expression of TRPA1 in the rat snake is low and not very different in the TG and the DRGs. There are no remarkable differences in the expression of TRPV1 in the TG versus the DRGs in either the rat snake or the python.
2. Since the expression of TRPA1 is dramatically higher in the TG of the pit snake but not in the TG of the non-pit snake, these data support the conclusion that the TRPA1 channel plays a role in the function of the pit organ.
3. If expression of the TRPA1 channel confers on a gene expression model system a temperature sensitivity in the range characteristic of the pit organ, that result would be strong evidence that the TRPA1 channel is the IR sensor in the pit organ.

FIGURE QUESTIONS

Figure 45.4 *Bombykol* has the function of attracting mates from a distance, so it has to diffuse widely. A territory-marking pheromone serves to indicate a specific place and therefore should not diffuse widely, so it would have a lower diffusion coefficient.

Figure 45.9 Several mechanisms can enable bilaterally placed ears to detect directionality of a sound: (1) The sound will be louder the closer the ear is to the source, and also the head creates a sound shadow for sounds coming from the side. (2) The sound will reach the closer ear sooner than the more distant ear. (3) If the sound is not coming from directly in front or in back, there will be a phase mismatch between the sound waves reaching the two ears.

Figure 45.13 Floaters in the eye would have to be in the vitreous humor.

APPLY WHAT YOU'VE LEARNED

1. According to the data, moths with disrupted tymbal organs displayed the same types of evasive maneuvers as moths with intact tymbal organs. There is no statistical difference in the evasive maneuvers made by silenced versus clicking moths. This finding demonstrates that the moths with the disrupted tymbal organs are still capable of “hearing” the echolocation signals coming from predatory bats and of responding with evasive maneuvers. If a significant difference had been seen in Figure A, this could indicate that tymbal organ disruption impeded a moth's ability to either hear the bat signals or respond with an evasive behavior.
2. According to the data, moths with intact tymbal organs were captured significantly less often than moths with disrupted tymbal organs. This is true for all silenced moths no matter what type of evasive maneuver they used to escape bat predation. If evasive maneuvers alone were responsible for moth escapes, we would not expect the number of captures between clicking and silenced moths to be significantly different. The fact that they are significantly different supports the hypothesis that the clicking of the tymbal organ

serves as an echolocation-jamming device, which when paired with evasive maneuvers results in fewer captures.

3. Different frequency sound waves cause flexion of the basilar membrane at different locations because the basilar membrane varies in thickness and stiffness. At the base it is most stiff and thick and is only flexed by high frequency pressure waves in the cochlear canals. At the apical end it is thinner and less stiff and is flexed by low frequency pressure waves in the cochlear canal. The bat can hear higher frequency sounds than humans can and therefore their basilar membranes must be thicker and stiffer at the basal end than are the basilar membranes of humans.

Chapter 46

RECAP 46.1

- 1a. The conscious sensory (afferent) stimulus of seeing a venomous snake prompts voluntary commands in the CNS to the muscles in the legs (efferent output) to run from the danger.
- b. The conscious sensory stimulus of the aroma of freshly baked bread can stimulate the autonomic responses of salivation and increased stomach activity.
- c. The unconscious stimulus of a fall in blood pressure can cause an involuntary command to increase heart rate.
2. Failure of the anterior region of the neural tube to close has the greatest effect on the telencephalon and results in lack of development of the cerebrum.
3. Areas of association cortex involved in reading and language are situated between the visual area in the occipital cortex and the auditory area in the temporal cortex. Reading integrates interpretation of visual images with the auditory patterns of spoken language.
4. Areas of the body that are shown by the two-point spatial discrimination test to be highly sensitive to touch are represented by large areas of somatosensory cortex.
5. The comparison of cortical capacity of humans with that of other mammals cannot be based just on brain size, because the human cortex is highly convoluted, giving the cortex a larger area. A higher percentage of the human cortex is devoted to association functions (association cortex) that increase cortical capacity.

RECAP 46.2

1. A knife wound to the left side of the neck could sever the sympathetic chain of ganglia on that side. This could break the connection between the preganglionic and postganglionic sympathetic neurons that innervate the pupil of the left eye and cause it to dilate.
2. A small spot of light on the retina can illuminate just the on-center of the receptive field of a ganglion cell and therefore activate it maximally. A larger spot of light would illuminate receptor cells around the on-center that have an inhibitory influence, and therefore decrease the activation caused by illuminating the center of that receptive field.
3. If the optic chiasm were cut right on the midline, the axons from the ganglion cells in the medial halves of the retina would not cross over to the opposite sides of the brain. As a result, the left eye would not see things in the left visual field and the right eye would not see things in the right visual field. Without input from both eyes, there would be no binocular cells and therefore no depth perception.

RECAP 46.3

1. Paralysis of skeletal muscles during REM sleep prevents the possibility that an individual would act out his or her dreams while in the dreaming state.
2. A person with a severed corpus callosum would not be able to describe in words an object in his left visual field, but he could draw it or point to a similar object in a picture.
3. Since H.M. was capable of immediate memory but could not retain longer-term declarative memories, we can conclude that the hippocampus is necessary for acquiring new declarative experiences and consolidating them into long-term memory.
4. Humans, great apes, elephants, and some marine mammals have an expanded insular lobe, which is involved in integrating physiological information from throughout the body, as well as social and emotional information, and may therefore generate a sense of self-awareness.

WORK WITH THE DATA, P. 986

1. The probability of this sequence out of a random firing of nine cells is first a function of the probability of that one combination from all of the combinations of cells that could constitute six elements of the nine possible. That would be $1/(9 \times 8 \times 7 \times 6 \times 5 \times 4) = 1/60,480 = 1.6 \times 10^{-5}$. Then, for the sequence, what is the probability that it would be in the correct order? There is one possible correct order of those six elements in $6 \times 5 \times 4 \times 3 \times 2 \times 1$ possible combinations or 1 in 720, thus the probability would be 1.4×10^{-3} . So the probability of recording those specific six elements out of nine in the correct order would be 2.24×10^{-8} .

2. The probability of recording four elements in the sequence in the proper order would be: $1/(9 \times 8 \times 7 \times 6) = 1/4,698 = 2.1 \times 10^{-4}$, and the probability of getting those four elements in the proper order would be $1/24$. Thus the probability of recording those specific four elements out of nine in the correct order would be $2.1 \times 10^{-4} \times 0.042 = 0.88 \times 10^{-3}$.
3. Both of these recordings have a probability of < 0.01 , so they would be considered significant low-probability events.
4. The time frame of the sequence recording during sleep is about five times faster than the occurrence of that sequence during wakefulness when the rat is running the maze.

FIGURE QUESTIONS

Figure 46.1 Hormones reach the CNS through the circulation. Neurohormones are secreted by neurons into the interstitial fluid, from which they can diffuse locally or enter the blood.

Figure 46.8 When an individual is stressed such as when speaking in public, the sympathetic nervous system is activated (fight-or-flight response), and that inhibits the activity of the salivary glands.

Figure 46.9 The blind spot in each eye corresponds to the location on the retina where the axons of the ganglion cells leave the retina to form the optic nerve. There are no photoreceptors at those locations.

Figure 46.10 The right and the left visual fields would be narrower and there would be no depth perception.

APPLY WHAT YOU'VE LEARNED

1. The subjects who were well rested gave correct answers to working-memory tests at least 95 percent of the time. Sleep-deprived subjects were almost 10 percent more likely to give incorrect answers.
2. Compared with well-rested subjects, sleep-deprived subjects took approximately 50 milliseconds longer to answer the questions, which could reflect decreased alertness. The results could also be due to an effect of sleep deprivation on cognitive processing time.
3. The left side of the cerebral cortex is responsible for processing and understanding language. Since the tests involved letter recognition and sequencing, this is likely to be the area most activated by the tests.
4. Sleep deprivation caused a 20-30 percent decrease in parietal lobe activity but only a 10-15 percent decline in prefrontal lobe activity. Testing this conclusion would require a statistical evaluation of the differences between activities in the two brain areas as a function of the sleep-deprivation treatment.

Chapter 47

RECAP 47.1

1. A sarcomere is bounded by the Z lines and consists of overlapping actin and myosin filaments. The actin filaments are anchored on the Z lines and do not extend all the way to the middle of the sarcomere. The myosin filaments are anchored on the M band at the center of the sarcomere but do not extend all the way to the Z lines. Thus there are regions where the actin and myosin filaments do not overlap (i.e., the I band and the H zone). When the muscle, hence the sarcomere, contracts, the myosin filaments move along the actin filaments toward the Z lines. As a result, the I band gets narrower. At the same time, the actin filaments move closer to the M band, so the H zone gets narrower.
2. One subunit of troponin anchors it to tropomyosin filaments. One subunit of troponin binds to the actin filament. One subunit binds Ca^{2+} . When Ca^{2+} binds to the troponin subunit, it causes a conformational change in the troponin, resulting in the tropomyosin filament pulling away from the myosin-binding site of the actin. Actin-myosin binding results in contraction of the sarcomere.
3. Rigor mortis is due to the loss of ATP that is required to break actin-myosin cross bridges. With the cessation of breathing and circulation at death, muscles do not receive oxygen and glucose from the blood and production of ATP through oxidative metabolism ceases. However, some ATP can continue to be produced by anaerobic metabolism, and the muscles with the most glycogen will be able to sustain anaerobic metabolism longer.
4. By destroying acetylcholinesterase, Malathione prevents the breakdown of acetylcholine released at the motor end plates, and as a result there is continuous and extreme activation of the muscle cell motor endplates. Action potentials continue to be fired in the muscle cell membranes resulting in tonic release of Ca^{2+} into the sarcoplasm and sustained activation of actin/myosin cross bridge formation.
5. Gap junctions enable sheets of cardiac or smooth muscle to contract as a unit. That makes it possible for cardiac muscle cells to work together to pump blood or smooth muscle cells to exert a unified function such as moving food through the gut. The individual control over skeletal muscle fibers enables fine control over complex movements.

RECAP 47.2

1. A skeletal muscle is made up of many muscle fibers. Each muscle fiber is innervated by one motor neuron constituting a motor unit, but one motor neuron may form synapses with multiple muscle fibers.

The nervous system can alter the frequency of action potentials in one motor unit, and it can increase the number of motor units activated in the same muscle.

2. Postural muscles must remain continuously contracted for long periods of time, but they are not generally used for quick, powerful movements.
3. The energy source for the sprint comes primarily from preformed ATP and creatine phosphate along with some contributions from glycolysis. These sources of ATP are rapidly mobilized. The longer 10-kilometer run requires production of ATP through oxidative metabolism, which requires O₂ transport and many more enzymatic reactions. It is therefore a slower source of ATP that cannot sustain as high a workload.

RECAP 47.3

1. Arthropods have external skeletons and therefore cannot grow without shedding (molting) their exoskeletons.
2. Since astronauts are losing bone mass, it is reasonable to hypothesize that the activity of their osteoclasts has increased, or the activity of their osteoblasts has decreased. It is possible that these changes are being induced by altered activity of their osteocytes in response to lack of weight-bearing stresses on their bones.
3. If the joint has a large force arm relative to the load arm, it can generate great pressures. If the force arm is short relative to the load arm, the end of the load arm can move over a large distance very quickly but cannot exert much pressure. Thus a larger force arm:load arm ratio for the jaw joint enables the jaws to apply great pressure over a small distance, whereas the smaller force arm:load arm ratio for the elbow enables the lower arm to move quickly over a larger distance but does not enable it to apply great pressure.

WORK WITH THE DATA, P. 1011

1.

2. The jump takes 50 ms (see Figure B), and the shortening in terms of muscle lengths is 7.5 mm/33.6 mm = 0.22 ML. So, velocity of muscle contraction in ML/sec = $0.22 / .05 \text{ sec} = 4.4$
3. The power generated by the jumping muscle is maximal at the observed mean jumping velocity.

WORK WITH THE DATA, P. 1013

1. If the workout capacity goes up with cooling, that suggests that the heat extraction is enabling more work, or in other words, decreasing muscle fatigue that otherwise limits workout capacity.
2. Cooling increased the work capacity for each workout in comparison to the previous workout, and over time, the rate of change of capacity was much greater with cooling than without. This difference in rate of change indicates that increasing work capacity (Figure A) leads to increased rate of conditioning (Figure B).

FIGURE QUESTIONS

Figure 47.4 If a motor neuron innervates only one or a few fibers, it is likely that those fibers are used in fine movements. If a single motor neuron innervates many muscle fibers of a muscle, it will be able to command strong, forceful movements.

Figure 47.6 ATP is necessary for skeletal muscle contraction to: (1) establish the ion gradient across the cell membranes, (2) break the actin-myosin bonds and “recock” the myosin heads, and (3) pump Ca²⁺ from the sarcoplasm into the sarcoplasmic reticulum.

Figure 47.11 A champion weight lifter is likely to have muscles with a high proportion of fast-twitch fibers.

Figure 47.13 The slopes of the curves are influenced by the time course of the mechanisms supplying the ATP supporting the activity. Because the first 10-20 seconds of high-level muscle WORK are supported by preformed ATP and CP, no further production of ATP and CP is involved. The production of ATP by glycolysis can produce ATP rapidly but not in large amounts, so the speed of performance goes

down in the first minute of intense exercise even though the production of ATP by oxidative metabolism is gradually increasing. Oxidative metabolism is a more efficient and sustainable producer of ATP, but it involves many more biochemical reactions than glycolysis, and cannot proceed as rapidly. Also, it is limited by the delivery of O_2 to the mitochondria, so the speed of sustained performance goes down further.

Figure 47.21 The knee joint is a class 3 lever

APPLY WHAT YOU'VE LEARNED

1. In both groups muscle glycogen fell to about 25 percent of its resting value by the point of fatigue. There were no significant differences ($P > 0.05$) in muscle glycogen at any time point in the two groups. Thus over 3 hours both groups depleted their muscle glycogen at about the same rate. Blood glucose in the placebo group fell steadily after the first hour, but blood glucose did not fall in the glucose-fed group, and blood glucose levels were significantly different in the two groups after the first hour. Both groups had similar levels of carbohydrate oxidation for the first 2 hours, after which the placebo group had declining carbohydrate oxidation levels that were significantly different from those of the glucose-fed group.
2. The difference between the two groups in time to fatigue was significant, and therefore the data show that carbohydrate feeding delayed muscle fatigue. Carbohydrate feeding also maintained blood glucose levels and the rate of carbohydrate oxidation. In addition, the data show that up until hour 3, this effect does not involve a slowing of muscle glycogen depletion.
3. For the glucose-fed group, there was no significant decline in muscle glycogen between hour 3 and 4, indicating that other sources of fuel were being metabolized once muscle glycogen was depleted. A possible explanation for these effects of carbohydrate feeding is that it enabled the subjects to support more of their metabolic work with carbohydrates. We can hypothesize that the placebo group had to compensate sooner with fuel sources other than carbohydrates.
4. The body uses a mixture of carbohydrate and fats as fuel for ATP production via oxidative metabolism. Fats are slower to be mobilized than carbohydrates. The blood FFA data indicate that the placebo group began to depend more on FFA metabolism after 1 hour of exercise, but the glucose-fed group did not increase utilization of FFAs until between 3 and 4 hours of exercise. At that time the subject depended less on muscle glycogen. Overall, the carbohydrate feeding extended the time that the subject could exercise without increasing utilization of FFAs
5. Suggest eating small snacks composed of simple sugars periodically during runs to prolong the time to fatigue.

Chapter 48

RECAP 48.1

1. At sea level, assuming a normal atmospheric pressure of 760 mm Hg, the PO_2 will be 20.9 percent of that, or 159 mm Hg. Therefore the P_{O_2} at 2,000 meters will be 127 mm Hg. When breathing air at two times the atmospheric pressure, the P_{O_2} will be 318 mm Hg.
2. Flatworms have a flat, thin body form, so all cells of the body are close enough to the surrounding environment that O_2 and CO_2 can diffuse directly between the cells and the environment. The two components of Fick's law reflected in these anatomical features are high surface area for diffusion, and minimal path length.
3. As water temperature increases, the O_2 content of water decreases (O_2 solubility decreases with increase in temperature), but since the fish's body temperature is at equilibrium with the water temperature, its metabolism increases (Q_{10} effect). Therefore the fish has to ventilate its gills more to satisfy its O_2 needs, and the WORK of gill ventilation increases O_2 demand even more
4. In going from sea level to high altitude, the partial pressure of O_2 in the inhaled air decreases, so the partial pressure gradient causing O_2 to diffuse into the body goes down. Since the partial pressure of CO_2 is extremely low at sea level, it does not decrease significantly at high altitude. Therefore the partial pressure gradient for CO_2 diffusing out of the body does not change.

RECAP 48.2

1. If ventilation (water) and perfusion (blood) of the gills are in the same direction (concurrent flow), then the concentration gradient of O_2 across the gills will gradually equilibrate somewhere between the maximum O_2 concentration of the water coming in and the O_2 concentration of the blood coming in. In countercurrent flow, it is possible for the O_2 concentration of the blood leaving the gills to be almost as great as the O_2 concentration of the water entering the gills
2. An important feature of avian lungs is the parabronchi, which enable air to travel unidirectionally through the lungs. When a bird inhales, the incoming air goes to the posterior air sacs. That fresh air flows into the parabronchi during the next exhalation. The subsequent inhalation causes air in the lungs to flow into

the anterior air sacs while fresh air flows into the posterior air sacs. The subsequent exhalation empties the anterior air sacs to the environment while the air in the posterior air sacs enters the lungs. Thus the through-pass of the parabronchi and the bellows action of the air sacs result in continuous, unidirectional flow of air through the avian lungs.

3. The amount of He in the system remains the same but becomes equally distributed in the spirometer and lungs. So the initial amount of He is $0.05 \times 30 \text{ L} = 1.5 \text{ L}$. The final amount of He is still 1.5 L, but it is distributed over $30 \text{ L} + \text{the person's FRV}$. Thus,

$$1.5 \text{ L} = 0.046 \times (30 \text{ L} + \text{FRV})$$

$$1.5 \text{ L} = 1.38 \text{ L} + 0.046\text{FRV}$$

$$0.12 \text{ L} = 0.046\text{FRV}$$

$$2.61 \text{ L} = \text{FRV}$$

RECAP 48.3

1. Some premature infants may be born before cells in their alveoli have started to secrete surfactant. Without surfactant, inflation of the lungs requires extra effort to overcome surface tension in the fluid lining the alveoli.
2. There is always tension between the pleural membranes because of the outward pull of the chest wall and the inward pull of the lung tissue. This tension keeps the lungs partially inflated even between breaths. A puncture of the chest wall allows air to enter space between the pleural membranes, equilibrating its pressure with atmospheric pressure. As a result, there is no longer a force maintaining partial inflation of the lungs.
3. The tension between the pleural membranes is maximal at the peak of inhalation because it is maintaining maximum distension of the lung tissue, but once the lungs are filled, air flow ceases and the alveolar pressure is the same as atmospheric pressure.

RECAP 48.4

1. Because of mixing with dead-space air, the maximum P_{O_2} in the alveoli is about 100 mm Hg, and hemoglobin can fully saturate at that P_{O_2} . The fact that mixed venous blood normally returns to the heart 75 percent saturated means that if the blood flows through any tissue that is very active metabolically, it has a reserve of O_2 that it can off-load to satisfy that local high demand.
2. When the concentration of 1,3-BPG in stored red blood cells decreases, so does the concentration of 2,3-BPG that can be generated by conversion from 1,3-BPG. As a result, the hemoglobin- O_2 binding/dissociation curve shifts to the left. Therefore the O_2 is more tightly bound to the hemoglobin and is not released for use by the respiring cells.
3. The conversion of CO_2 to H_2CO_3 and then to HCO_3^- is a reversible reaction depending on the concentrations of reactants and products. In the respiring tissues the PCO_2 is high and drives the reaction in the red blood cells toward HCO_3^- , which moves into the blood plasma in exchange for Cl^- . In the alveoli, the PCO_2 is low, so this entire suite of reactions is driven in reverse, meaning that the diffusion of CO_2 out of the red blood cells causes HCO_3^- to be moved back into the red blood cells to be converted back to H_2CO_3 and then to CO_2 .

RECAP 48.5

1. During tidal breathing, a regular cyclical pattern of firing of respiratory motor neurons in the dorsal respiratory group of the medulla drives muscle contractions of the diaphragm. The need for increased respiratory gas exchange is first met with an increase in the rate of that oscillatory pattern of firing in the dorsal respiratory group, but as the need increases, the ventral respiratory group is recruited and those neurons drive contractions of the intercostal muscles, increasing the volume of air exchanged with each breath.
2. When you go to high altitude, the diffusion gradient for O_2 decreases as atmospheric pressure decreases. However, the diffusion gradient for CO_2 does not change; ambient CO_2 is close to 0 at sea level and also at high altitude. Therefore breathing to satisfy O_2 needs results in a greater loss of CO_2 than at sea level. Since CO_2 is the major stimulus for respiration, respiration slows or ceases until the PCO_2 returns to a level that stimulates breathing.
3. Because the carotid and aortic bodies have high metabolic rates, they are compromised by a decrease in their O_2 supply, whether it is because of decreased blood flow or decreased PO_2 in the blood.

WORK WITH THE DATA, P. 1030

1. Since helium is not absorbed by the respiratory system, the amount of helium remains the same after breathing from the air reservoir as before, but it is distributed in both the reservoir air and the functional residual volume (FRV) of the patient. Using the helium dilution method, we can calculate the FRV.
 $0.05 \times 30 \text{ L} = 0.044 (30 \text{ L} + \text{FRV})$

$$1.5 \text{ L} = 1.32 \text{ L} + 0.044 \times \text{FRV}$$

$$(1.5 - 1.32)/0.044 = \text{FRV} = 4.1 \text{ L}$$

Subtracting the expiratory reserve volume of 1.5 L gives a residual volume of 2.6 L.

- The patient is always short of breath because the PO_2 in his alveoli is seriously diminished by the stale air in his very large residual volume as well as in his increased FRV during tidal breathing.

WORK WITH THE DATA, P. 1037

- O₂ available in venous blood:
 Total venous blood = $355 \text{ kg} \times 0.148 \times 0.66 = 34.7 \text{ kg}$
 Total venous hemoglobin = $34.7 \text{ kg} \times 0.58 \times 0.24 = 4.8 \text{ kg}$
 Total venous O₂ available = $4.8 \text{ kg} \times 1.34 \text{ L/kg} \times 0.9 = 5.8 \text{ L}$
- O₂ available in myoglobin:
 Total amount of myoglobin: $355 \text{ kg} \times 0.33 \times 44\text{g/kg} = 5.2 \text{ kg}$
 O₂ bound to myoglobin: $5.2 \text{ kg} \times 1.34 \text{ L/kg} = 7\text{L}$
- Total O₂ reserves at beginning of dive:
 $2.5 \text{ L} + 5.8 \text{ L} + 7.0 \text{ L} = 15.3 \text{ L}$
- Maximum sleep episode = total O₂ reserves divided by the diving metabolic rate. So, 5.3 L divided by the rate of O₂ consumption which for a long dive would be $0.0035 \text{ L/kg min} \times 355 \text{ kg}$. So, $15.3\text{L} / 1.24 \text{ L/min} = 12.3 \text{ min}$, which corresponds well with the observed maximum sleep episode of 13.5 min.
- Assuming the overall dive metabolic rate of $4.5 \text{ mL O}_2/\text{min kg}$, the maximum dive time would be $15.31/(0.0045 \text{ mL O}_2/\text{min} \times 355 \text{ kg}) = 10 \text{ min}$, which is much less than the observed dive times.

FIGURE QUESTIONS

Figure 48.6 If the flow rate of the water were increased, or the flow rate of the blood were decreased, it would be possible to maximally saturate the blood with a concurrent exchanger. This exchange would be less efficient than countercurrent exchange, however.

Figure 48.10 If there are 23 branchings of the airways, each giving rise to 2 new branches, the total number of terminal airways would be 223, or 8,388,608.

Figure 48.13 The hemoglobin would not fully saturate with O₂ at 100 mm Hg P_{O_2} .

APPLY WHAT YOU'VE LEARNED

- In Figure A, in the 15 minutes that the spiracles were open, the intratracheal O₂ level increased from 19 to 142 mm Hg. In the 22-23 minutes in which the spiracles were closed, the intratracheal level of O₂ dropped from 142 to approximately 37.5 mm Hg. In the approximately 70 minutes that the pupae entered the fluttering phase, the intratracheal O₂ level fluctuated between 37.5 and 18.75 mm Hg. In Figure B, the first chamber's atmospheric O₂ concentration was 48 mm Hg, but the fluttering phase kept the intratracheal O₂ levels at a fairly consistent 36.75 mm Hg. In the second chamber, the atmospheric O₂ levels were 159 mm Hg. The fluttering phase allowed some fluctuation in the intratracheal O₂ levels, from a high of roughly 38.25 mm Hg to a low of roughly 36 mm Hg. In the third chamber, atmospheric levels of O₂ were almost double normal atmospheric O₂ levels, at 301.5 mm Hg. But the fluttering phase kept the intratracheal O₂ level at an almost constant 30 mm Hg.
- When the tracheal tubes open, the atmospheric O₂ diffuses into the tubes, bringing the intratracheal O₂ level close to normal atmospheric O₂ levels (159 mm Hg). However, over the approximately 23 minutes that the spiracles are closed, the O₂ levels are slowly depleted as more O₂ is dissolved into the hemocoel and distributed to all of the cells to be used in aerobic respiration. We could predict that this O₂ level would continue to decline, approaching zero, if it were not for the fluttering phase. The fluttering phase appears to allow CO₂ to escape into the atmosphere while also allowing small amounts of O₂ to enter the tracheal tubes and maintain O₂ levels at a fairly constant level.
- A delicate balance must be maintained between intratracheal O₂ levels and atmospheric O₂ levels. When atmospheric levels of O₂ are normal (middle graph in Figure B), the fluttering phase allows CO₂ release and replacement of O₂ to seek a fairly constant level of O₂ within the trachea. In a low-oxygen environment (first graph in Figure B), the fluttering phase is increased, compared with a normal atmospheric O₂ level. Beginning at a lower level of O₂ at the time of spiracle closure would make it necessary to increase the amount of fluttering to keep O₂ levels at an appropriate intratracheal concentration for adequate aerobic respiration. However, when atmospheric O₂ levels are abnormally high, the fluttering phase is greatly diminished (third graph in Figure B). Opening the spiracles as often as what is seen under normal atmospheric O₂ levels could expose cells to higher than normal O₂ levels. These levels could prove detrimental to insect cells. Therefore decreasing the amount of fluttering would be one way to prevent too much O₂ from entering the tracheal tubes and reaching a toxic cellular level.

Chapter 49

RECAP 49.1

1. Circulatory systems supply exercising muscle cells with oxygen and nutrients. They also take CO₂ and heat out of muscles.
2. A sponge has water channels throughout its tissues, which means that the external medium can circulate close to all of the sponge's cells, where exchanges of nutrients, oxygen, and wastes take place.
3. Hemolymph is the extracellular fluid in animals with an open circulatory system. In animals with a closed circulatory system, blood plasma is the extracellular fluid contained in the heart and blood vessels, and interstitial fluid is the extracellular fluid outside the circulatory system. Blood contains cellular elements in addition to plasma.
4. The fight-or-flight response involves increasing blood flow to tissues that are necessary for action, such as the skeletal muscles, and decreasing blood flow to tissues that are not necessary for action, such as the gut. A closed circulatory system can increase blood flow by increasing pressure, and it can also direct that blood flow to critical tissues by changing the resistance in the vessels leading to those tissues.

RECAP 49.2

1. Deoxygenated blood returns from the systemic circulation in veins that converge on the sinus venosus that leads to the atrium. From the atrium, blood flows into the single, muscular ventricle. When the ventricle contracts, blood under pressure flows into the elastic bulbus arteriosus. The elastic recoil of the bulbus arteriosus maintains a continuous blood flow through the gills where respiratory gas exchange occurs. The oxygenated blood from the gills flows through the systemic circuit.
2. The direction of O₂ diffusion across the gill membranes depends on the PO₂ gradient between the blood and the water flowing across the gills. By taking air into its lungs, the fish can maintain a higher PO₂ in its blood than in the surrounding water. As a result, O₂ diffuses from the blood to the water, increasing the PO₂ in the water surrounding the eggs.
3. Ectothermic reptiles have a left and a right aorta. Except for the crocodilians, the ventricles are not completely divided and thus blood from the right ventricle can flow either into the right aorta or the pulmonary aorta. When the animal is resting or submerged and not breathing, the resistance in the lung circuit is high and blood from both ventricles flows into the aortas. When the animal is breathing, resistance in the lung circuit goes down, and blood from the right ventricle flows into the lung circuit while blood from the left ventricle flows into the aortas. In crocodilians there is complete separation of the ventricles and the right aorta opens into the right ventricle. But, just where the aortas leave the heart there is a connection between them. When the animal is breathing and resistance in the lung circuit is low, back pressure from the left aorta closes the valve between the right ventricle and right aorta so all blood from the right ventricle flows to the lungs. When resistance in the lung circuit is high, then pressure in the right ventricle is high enough to open the right aortic valve and blood from the right ventricle flows in the right aorta to the systemic circuit.
4. At birth, when the newborn starts to breathe, the resistance in the pulmonary circuit falls. If the ductus arteriosus does not close, the higher pressure in the left ventricle will pump blood into the pulmonary circuit through the open (patent) ductus arteriosus. This will cause the pulmonary circuit to become congested and the systemic circuit to be deprived of oxygenated blood.

RECAP 49.3

1. Aortic valve stenosis would decrease the flow of blood into the aorta. Consequences would include decreased pressure in the aorta and major arteries and decreased blood flow to tissues, causing fatigue and shortness of breath. Pressure in the left ventricle would increase, as would its work load. Blood could back up in the pulmonary circuit, causing pulmonary hypertension. Pulmonary valve stenosis would decrease blood flow to the lungs and therefore decrease delivery of oxygenated blood to the left heart, causing fatigue and shortness of breath. The pressure in the right ventricle would increase, as would pressure in the venous return vessels.
2. Contraction of the myocardium depends on the presence of Ca²⁺ ions in the sarcoplasm. Increasing Ca²⁺ in the sarcoplasm prolongs the duration of the Ca²⁺ pulse resulting from the cardiac action potential. Thus the heart beats more strongly, contractions last longer, and cardiac output increases.
3. Stenosis of the aortic valve should produce a heart murmur during systole, as that is when pressure in the left ventricle is pushing blood through the aortic valve. Prolapse of the aortic valve should create a heart murmur during diastole, as that is when greater pressure in the aorta is pushing blood back into the ventricle through the prolapsed aortic valve.

RECAP 49.4

1. The partial pressure of O₂ is lower at high altitudes; therefore the athletes experience hypoxia and acclimate to the high altitude environment by producing more red blood cells. As a result, when they compete at lower altitudes, they have greater aerobic capacity.
2. Blood clotting is a massive event involving large numbers of cells and signals, yet it can be initiated by a

small wound that exposes collagen fibers. Platelets that come into contact with those fibers are activated. They become sticky and stick to other platelets, which also become activated. The activated platelets release chemical signals that trigger a long line of clotting reactions, and with each step, the reaction grows. Thus a small event triggers a larger and larger number of events leading to clotting—a cascade of events.

3. Arterioles are called resistance vessels because of the smooth muscles in their walls that can constrict the vessels and increase their resistance. Changing the resistance of different arterioles allows blood flow to be directed to the tissues and organs that need it the most. Veins are called capacitance vessels because their thin walls with many elastic fibers can stretch to hold larger volumes of blood. When the body is at rest, all of the blood does not have to circulate to serve the body's needs, so a large proportion of it can be held in reserve in capacitance vessels.
4. The blood proteins are responsible for the osmotic pressure that draws interstitial fluid back into the capillaries. If the blood proteins are metabolized, the blood osmotic pressure drops and more plasma that leaves the capillaries due to hydrostatic pressure remains in the interstitial spaces. Thus interstitial fluid accumulates in the abdominal cavity and the extremities.

RECAP 49.5

1. [Figure 49.19](#) shows that a drop in blood flow to a tissue due to a fall in MAP results in autoregulatory responses that decrease the resistance to flow in that tissue. Any decreased resistance in the systemic circuit will cause a drop in MAP, further depriving that tissue of O₂ and nutrients and increasing the autoregulatory response. With this positive feedback loop, the autoregulatory response can worsen the problem that initiated it.
2. The sympathetic division of the ANS stimulates vasoconstriction in tissues not essential for a fight-or-flight response, such as the digestive system and the skin. This increase in total peripheral resistance results in a rise in MAP. The sympathetic innervation of the heart causes it to beat faster and more strongly, also contributing to a rise in MAP. The parasympathetic division of the ANS has opposite effects, slowing the heart and decreasing MAP.
3. Baroreceptors are firing at a rate midpoint in their range when blood pressure is normal. Therefore they have the potential to either decrease or increase their firing rate, depending on whether MAP falls or rises. They therefore contribute to regulatory responses to both rises and falls in MAP.
4. Autoregulatory mechanisms operate at the local level to dilate or constrict arterioles in response to local changes in the chemical environment. These changes in arteriole diameter affect the amount of blood reaching local tissues. As these changes occur, they have an effect on the body's blood pressure, which is detected by baroreceptors that elicit neural and hormonal signals that cause widespread cardiovascular changes throughout the body.

WORK WITH THE DATA, [P. 1055](#)

1. Comparing mutant mice not CsA treated, but treated with or without RNAi, the left ventricular wall thickness (LVWT) of the controls was 0.96 ± 0.12 and that of the RNAi-treated mice was $0.70 \pm .088$. A *t*-test for the probability that these two mean LVWTs should be the same gives $P = 0.0025$, indicating that they are significantly different: the RNAi-treated animals had significantly lower LVWT.
2. Comparing mutant mice that did receive CsA but did or did not receive RNAi treatment, the LVWT of the control mice was 1.66 ± 0.22 and that of the RNAi mice was $0.85 \pm .06$. A *t*-test calculates $P < 0.001$, indicating that these two mean LVWTs are significantly different.

FIGURE QUESTIONS

[Figure 49.4](#) If these curves were for the right ventricle, the volume curve would be the same, but the pressure curves during systole would be lower.

[Figure 49.9](#) The breadth of the ventricular muscle action potential is important because it determines the duration of systole and therefore the time available for the emptying of the heart. More complete emptying means greater stroke volume.

[Figure 49.10](#) An occasional block of the AV node could result in a lengthening of the interval between the P and R waves (the PR interval) on the ECG and possibly a missed beat. A long-lasting block of the AV node could result in complete dissociation between the atrial rhythm and the ventricular rhythm.

APPLY WHAT YOU'VE LEARNED

1.

Blood from the right ventricle is blocked from exiting the right aorta by the surgery. Blood from the right ventricle can pass only through the pulmonary artery. This change converted the crocodilian heart into a heart similar to that of a bird, because a bird heart obligates the blood to go from the right ventricle to the lungs with no opportunity for bypass. In a bird, blood goes from the right ventricle to the lungs to the left atrium to the left ventricle to the body and then back to the right atrium and right ventricle again.

In a crocodilian, the blood can go from the right ventricle to either the lungs or the body

2. When an alligator is diving and spending time underwater, it is not actively breathing. In these instances (which can extend for long periods of time), the animal does not need to expend energy to pump blood through the lungs. An adaptive advantage is the ability to conserve energy by not pumping blood to the lungs when there is no benefit to be gained from doing so.
3. If bypassing the pulmonary circuit conserves energy in these animals, an indication might be that growth rates of control animals would have been higher than those of experimental animals, since control animals would have more energy available to divert to growth. However, if we require a P value < 0.01 to conclude that there is a significant difference between the control and experimental groups for both sedentary and exercised animals, there are no significant differences in body mass or body length. This indicates that growth rates between control and experimental animals were similar, suggesting that the pulmonary bypass capability confers no adaptive advantage in terms of growth of juvenile alligators, even when they are stressed by exercise. Therefore these data alone do not allow us to say that the shunt affords a significant conservation of energy related to growth.
4. An investigator could compare the duration of breath-hold dives in experimental and control animals. This indicator would provide a measure of the time animals can spend not breathing, which would be an advantage in their ability to survive underwater for extended periods of time. Animals with greater dive times could evade predators more easily and also gain greater predatory advantages themselves by their ability to lie in wait for prey for extended times underwater.
A second indicator could be the amount of food consumed and waste produced by experimental and control animals under otherwise identical conditions. This indicator could be used to compute calories burned and would support the hypothesis if experimental animals burned more calories than control animals, since experimental animals would need more energy to go about their daily activities.
A third indicator would be the number of eggs produced by female alligators in experimental and control groups. To support the hypothesis, the results from this study would have to show that experimental females produce fewer eggs over a defined time period than control females. The quantity of eggs is related to the amount of energy the animals have available to put toward reproduction, and loss of the shunt may cause experimental animals to have less energy to expend in producing eggs.

Chapter 50

RECAP 50.1

1. When gray whales are migrating and on their wintering grounds, their energy source is their stored fat (blubber). Fat has a high energy content and low water content and therefore is ideal for long-term storage of energy with minimal mass. It also contributes to the buoyancy of the whale body.
2. Vitamin A is fat-soluble and can accumulate in the body. Vitamin C is water-soluble and rapidly excreted in the urine, so a toxic level of it cannot accumulate.
3. The micronutrient iron is largely recycled in the body, but due to menstrual blood loss, premenopausal women do lose iron each month.
4. If proteins were added to a solution delivered into the blood, it would stimulate an immune response in the patient to foreign proteins. Therefore it is essential to supply all amino acids in such a mix.

RECAP 50.2

1. Herbivores must spend much time feeding because their food has low energy content and requires considerable processing both mechanically (chewing) and chemically (digestion).
2. All of the digestive enzymes act through hydrolysis of their substrates.
3. Antibiotic therapy can greatly diminish or alter the gut microbiota and therefore result in altered digestion.
4. The symptoms are due to damage to the villi. Damaged villi are less effective at absorbing the products of digestion and therefore contribute to undernutrition and even lack of micronutrients such as iron. Unabsorbed digestive products pull water into the gut, resulting in diarrhea, and also support microbial metabolism, leading to bloating. Damaged villi compromise the surface area available for digestion, affecting fat absorption as well as absorption of nutrients that require transport. The undigested fat results in fatty stools.

RECAP 50.3

1. The tongue pushes the chewed food to the back of the mouth stimulating the swallowing reflex that through activation of many muscles pushes the food into the esophagus. Stretching of the smooth muscle in the esophagus stimulates contraction of that smooth muscle pushing the food toward the stomach. The directionality of this movement is facilitated by the enteric nervous system causing the smooth muscle ahead of the bolus of food to relax. When the bolus of food reaches the esophageal sphincter, that anticipatory wave of relaxation opens the sphincter allowing the food to enter the stomach. The coordination of smooth muscle contraction and relaxation creates the waves of peristalsis that generally

moves the food in the esophagus towards the stomach even in the absence of gravity.

2. Stomach acid is produced by chief cells in the gastric pits of the stomach. In these cells, carbonic anhydrase catalyzes the hydration of CO_2 to produce H_2CO_3 , which dissociates into HCO_3^- and H^+ . The H^+ is transported across the pit lumen side of the cell in exchange for K^+ . The HCO_3^- is exchanged across the opposite end of the cell into the interstitial fluid in exchange for Cl^- ions. The excess K^+ in the cell leaks out the luminal end and is pumped back in via the H^+/K^+ exchanger. Thus the concentration of H^+ in the stomach lumen and the separation of HCO_3^- in the interstitial fluid depend on the anatomical integrity of the stomach wall. If that integrity is destroyed, the H^+ cannot be separated from the HCO_3^- and there will be no pH change.
3. Bile emulsifies fats in the diet, creating tiny micelles that present a large surface area for the action of water-soluble lipases. Bile prevents the fatty micelles from coalescing into larger fat globules with a smaller surface area. Equivalent molecules are not required in the lymph and blood because the fats in lymph and blood are incorporated into lipoproteins that are coated with water-soluble proteins.
4. The gut microbiota is a significant source of nutrition for ruminants because their microbiota grow on the ingested food in the rumen and reticulum before the semidigested food is exposed to the HCl and digestive enzymes of the stomach and small intestine. In humans, abundant microbiota are present in the small and large intestine and therefore are not killed by the stomach acid and digested in the upper region of the small intestine, where they could otherwise serve as a major source of nutrition.
5. The ruminant does not produce the cellulose hydrolyzing enzymes necessary to digest the plant materials it eats. The rumen and reticulum have cultures of microorganisms that produce cellulases and break down the plant matter. The resulting fermenting mixture of plant matter and microorganisms moves into the omasum, where water is reabsorbed. From the omasum, the mass of semi-digested plant matter and the associated microorganisms move to the abomasum (true stomach) that secretes HCl , which aids digestion and kills the microorganisms that are an important component of the animal's nutrition.
6. If even a small amount of pepsinogen is activated by hydrolytic cleavage to produce the active enzyme pepsin, that pepsin will act on additional pepsinogen to release more pepsin molecules creating an autocatalytic cascade. This is an example of positive feedback in which a product of a reaction (pepsin) stimulates still more reaction ($\text{pepsinogen} \rightarrow \text{pepsin}$), which amplifies formation of the product of that reaction (pepsin).

RECAP 50.4

1. Introducing nutrient solutions into the jejunum would not stimulate release of secretin or CCK, therefore there would not be bile secretion to emulsify large complex lipids and there would not be pancreatic enzymes to digest complex carbohydrates and proteins. Thus, the jejunal formula would have to consist of medium to short chain fatty acids and partially hydrolyzed carbohydrates and proteins.
2. The three classes of lipoproteins differ in their relative compositions of protein, triglycerides, and cholesterol. The high-density lipoproteins have the lowest percentage of triglycerides and deliver cholesterol from tissues to the liver for excretion as bile. Low-density lipoproteins have less protein and triglyceride and more cholesterol. These particles have transferred most of their triglycerides to adipose and other cells and are left with a lot of cholesterol that can be deposited into the walls of arteries. Very low-density lipoproteins consist mostly of triglycerides, which they transfer to adipose cells, resulting in the production of low-density lipoproteins.
3. In both muscle and liver, insulin promotes the uptake of glucose and its incorporation into glycogen. When insulin levels fall, the effects are different in liver and muscle, in that in liver the reduced levels activate glucose phosphatase. This makes it possible for the glucose produced by the breakdown of glycogen to be released into the interstitial fluid. This process does not occur in muscle, so the glucose is trapped in the muscle.
4. In the experiments in which the lateral hypothalamus or the ventromedial hypothalamus was lesioned and subsequent changes in body mass measured, the animals either gained or lost a large amount of mass, but they eventually plateaued at a new level, indicating the continued ability to regulate, but at a different level.
5. Pyruvate and lactate produced by muscles working anaerobically enter the circulation and are taken up by the liver, where they are converted to glucose by processes of gluconeogenesis. This glucose can then return to the blood and support further glycolysis by the muscles.
6. Rats that have a mutation that eliminates their production of leptin eat more and become obese. If these rats are joined parabiotically with normal rats that produce leptin, the obese rats eat less and lose mass.

WORK WITH THE DATA, P. 1078

1. The average fasting blood glucose level was 11.00 mM for the lard-fed mice and 10.30 mM for the fish-oil-fed mice. These values are significantly different at the $P < 0.05$ level according to a two-tailed,

- non-paired *t*-test, (these calculations can be done in Excel).
- The average fasting blood insulin level was 3.96 ng/mL for the lard-fed mice and 1.09 ng/mL for the fish-oil-fed mice. A *t*-test, two-tailed, non-paired showed that $P < 0.0001$ which is highly significant.
 - The time course of the response to an insulin challenge can be plotted. *T*-tests can then be used to see which points are significantly different.
The 30-minute values are not significantly different, but the rest of the time points are: 60 minutes, $P < 0.005$; 90 and 120 minutes, $P < 0.001$.
 - The lard-fed mice were less responsive to insulin and had a slightly higher fasting blood glucose level. This suggests an impairment of their carbohydrate metabolism. The fish-oil-fed mice had a more robust response to the insulin challenge.

FIGURE QUESTIONS

Figure 50.14 Without a gallbladder, the release of bile into the small intestine is continuous and slow, meaning a large amount of fat passing through cannot be optimally emulsified and digested. As a result it passes through the small intestine without being absorbed and produces fatty stool and diarrhea.

Figure 50.15 The position of the rumen and reticulum before the abomasum allows large populations of gut microbiota to grow and break down the ingested plant material before passing into the true stomach, where they are killed by stomach acid.

Figure 50.16 The fact that CCK and secretin can slow the stomach yet stimulate the pancreas means that these two hormones can regulate the passage of food through the digestive tract at a rate that enables complete digestion.

Figure 50.17 The uptake of glucose by cells of the nervous system does not depend on hormonal stimulation—it depends only on the concentration difference of glucose between the interstitial fluid and the cell interior. All of the hormone actions in this figure refer to mechanisms aimed at maintaining a constant blood glucose concentration, and this is the variable that guarantees adequate glucose supply for the nervous system.

APPLY WHAT YOU'VE LEARNED

- The higher triglyceride levels in winter indicate a greater dependence on fat metabolism during winter, and this is supported by the decrease in winter of lactate, a product of glycolysis (carbohydrate metabolism), and the increase in succinate, which is a citric acid cycle intermediate. Since both carbohydrate and triglyceride metabolites enter the citric acid cycle as acetyl CoA, these data support the idea of an increase in dependence on fat metabolism during winter.
- The data show significant changes in three highly abundant phyla and no change in one highly abundant phylum. Thus we can conclude that there are major seasonal changes in the gut microbiome. These changes could be due simply to the presence or absence of food in the gut over a substantial period of time, or the changes could play a role in the different metabolic states of the bears in summer and winter.
- The data indicate that the summer microbiota promote greater mass and fat gain than winter microbiota. Two hypotheses that could explain this difference are that (1) some signal from the summer microbiota stimulates greater food intake, and (2) the summer microbiota is more efficient at facilitating digestion when there is high nutrient flow through the gut.
- The data suggest that a seasonal change in the gut microbiome of the bears supports and may promote increased food intake and digestive efficiency in the summer months. The change from the summer to

the winter gut microbiome may result from some microbial species being able to survive a long duration of fasting, or the change in microbiome may have a functional significance in altering energy metabolism to promote storage in the summer and conservation in the winter.

Chapter 51

RECAP 51.1

1. A freshwater vertebrate has to osmoregulate by conserving salts and excreting water. Having a closed circulatory system makes it possible to use pressure to filter the extracellular fluid to excrete water without the loss of salts and other solutes.
2. An animal that lives in the intertidal may be isolated in tidal pools that can be highly diluted by rain or highly concentrated by evaporation. *Artemia* may survive by osmoconforming over a wide range of salinities, but it cannot survive at the extremes of fresh water or saturated salt solutions without being able to osmoregulate. *Artemia* uses active transport of ions across its gills to regulate hypertonically in very dilute environments and to regulate hypotonically in highly concentrated environments.
3. Bundles of secretory tubules drain into the salt gland ducts. The cells of those tubules actively transport Cl^- ions into the lumen. Na^+ follows, then water flushes the contents of the tubules into the duct.

RECAP 51.2

1. Ammonia is toxic and must be either excreted rapidly or detoxified. Ammonia is highly soluble in water and diffuses rapidly, so in fish, ammonia can diffuse into the blood and then be lost to the environment by continuous diffusion across the gill membranes. Because mammals are tidal breathers, the ammonia in their blood would have to reach higher levels to be lost by diffusion across alveolar membranes, so mammals detoxify ammonia by converting it into urea or uric acid.
2. Uric acid is considerably less soluble than urea. It precipitates out of solution in humans, in whom the total osmolarity of extracellular fluid is 300 mosm/L and therefore the contribution of uric acid to that concentration is considerably less than 300 mosm/L. Sharks and rays could not produce an extracellular osmolarity greater than that of seawater by retaining uric acid.
3. Most terrestrial animals have to conserve water. The advantage of excreting uric acid is that it can be precipitated out of solution in the excretory system, enabling the reabsorption, and therefore conservation, of water.

RECAP 51.3

1. Freshwater flatworms have to deal with a constant influx of water into their extracellular fluids by osmosis. The flame cells make it possible to filter that extracellular fluid into the protonephridia without loss of solutes, and the protonephridia can further process the filtrate by secretion and reabsorption to increase elimination of wastes and conserve solutes.
2. The blood plasma is filtered in capillaries to produce the coelomic fluid, and the two are similar in composition. The coelomic fluid is processed in the metanephridia through processes of tubular secretion and reabsorption to become the urine that is excreted from the body.
3. The insect excretory system eliminates nitrogenous waste as uric acid. By actively reabsorbing Na^+ and K^+ in the hindgut and rectum, the insect concentrates the waste fluid to the point that uric acid precipitates out of solution thus lowering the osmolarity of the contents of the hindgut and rectum and enabling more reabsorption of water due the active reabsorption of Na^+ and K^+ .

RECAP 51.4

1. To move into more arid terrestrial habitats, vertebrates had to minimize their water loss and their need to have access to standing water to practice external fertilization. Whereas both amphibians and reptiles evolved various adaptations to decrease evaporative water loss from their skins, only reptiles gained independence from needing standing water to reproduce, by the evolution of the amniote egg. However, the amniote egg requires fertilization before it is encased in a protective shell, and thus the evolution of internal fertilization paralleled the evolution of the amniote egg.
2. The afferent arterioles bring blood into the glomerulus at high pressure to support filtration. The efferent arterioles carry the remaining blood from the glomerulus to the capillaries serving the renal tubules, where secretion and reabsorption of solutes occur.
3. The anatomical components of the glomerular filtration mechanism are: fenestrations in the glomerular capillary walls, the basal lamina of the capillary endothelial cells, and the slits between the processes of the podocytes of Bowman's capsule.
4. The composition of the urine is made different from the composition of the blood by processes of selective active reabsorption and secretion by the renal tubules.

RECAP 51.5

1. The highest concentration of mitochondria would be in the renal cortex because of all of the active transport mechanisms in the convoluted tubules. The lowest concentration would be at the bottom of the renal medulla where there are only thin regions of the loops of Henle. The intermediate concentration would be in the upper level of the renal medulla because of the active transporters of Na^+ in the thick ascending limb of the loop of Henle.
2. The thick ascending limb of the loop of Henle actively transports Na^+ from the tubular fluid to the extracellular fluid, and Cl^- follows. The increase in NaCl in the extracellular fluid of the medulla pulls water out of the descending limb osmotically, increasing the concentration of the tubular fluid. Since the ascending limb is not permeable to water, the more concentrated tubular fluid cannot pull water into the ascending limb. When it reaches the thick ascending limb, more NaCl is pumped out into the extracellular space. Through this mechanism, the concentration of the extracellular fluid in the renal medulla is maintained higher than the blood osmolarity.
3. The desert rat would have longer loops of Henle and therefore a longer renal medulla. The desert rat has evolved under selective pressure to conserve water. One way of doing that is to produce a more concentrated urine. The longer the loops of Henle, the greater the concentration gradient that can be created in the renal medulla, so the desert rat should have longer loops of Henle.
4. Bicarbonate in the blood is filtered into the tubular fluid, but the H^+ ions transported into the tubular fluid by the tubule cells combine with that bicarbonate to produce H_2CO_3 (carbonic acid), which dissociates into H_2O and CO_2 . The CO_2 diffuses into the tubule cells, where its hydration to H_2CO_3 is catalyzed by carbonic anhydrase. The resulting HCO_3^- is transported across the basal end of the tubule cells and into the interstitial fluid.

RECAP 51.6

1. The afferent and efferent arterioles regulate GFR by changing their resistance to flow. When blood pressure rises, the afferent arterioles respond by constricting and increasing their resistance. When blood pressure falls, the efferent arterioles respond by constricting and increasing their resistance. Constriction of the afferent arterioles decreases GFR, and constriction of the efferent arterioles increases GFR. Constriction of the afferent arterioles is due to the general property of smooth muscle - when stretched, it responds by contracting.
With a decrease in blood pressure and therefore a decrease in GFR, the feedback information is a fall in solute concentration in the distal tubule. In response, the macula densa cells signal the afferent arterioles to dilate and cause the efferent arterioles to constrict by releasing renin, which initiates the conversion of angiotensinogen to angiotensin, which in turn stimulates the efferent arterioles to constrict.
2. The secretion of renin and the resulting production of active angiotensin are triggered by a fall in blood pressure and therefore a fall in GFR. One action of the renin-angiotensin-aldosterone system is to increase water reabsorption from the kidney to maintain blood volume. To reabsorb water, it is necessary to increase the reabsorption of Na^+ to create the osmotic gradient that will pull water from the tubule fluid into the tubule cells. However, if the exchanger moved Na^+ and K^+ one for one, it would not create an osmotic gradient.
3. The chicken broth has the same osmolarity as the body fluids, so its absorption from the gut would not increase the blood osmolarity, but it would increase blood volume and blood pressure. The increase in blood pressure would stimulate the carotid baroreceptors, resulting in an inhibition of ADH release. As a result of decreased ADH, the kidney would reabsorb less water and therefore produce more urine. In addition, the increased blood volume would stimulate the release of atrial natriuretic peptide, causing increased secretion of Na^+ and therefore increased loss of water, thus reducing fluid volume, blood volume, and blood pressure.

WORK WITH THE DATA, [P. 1104](#)

1. The average urine flow rate over the first hour is 0.18 g/g body mass/hr and for a 30-g bat would be 5.4 g. Blood intake = $0.60 \times 30 \text{ g} = 18 \text{ g}$. Therefore the percent of the ingested volume excreted in the first hour would be 30%.
2. The maximum concentrating factor in this experiment is $3,400 \text{ mosm}/300 \text{ mosm} = 11.3$.
3. Extrapolating the missing data by connecting the two curves with a straight line would not be reasonable because the urine flow rate falls close to its lowest level at 2.5 hours (150 minutes). It is reasonable to expect that the urine osmolarity would be close to maximum at this time.

FIGURE QUESTIONS

Figure 51.4 For the freshwater planarian, the excretory product would be hypotonic to the interstitial fluid because the animal has to be excreting excess water that is entering its body by osmosis.

Figure 51.6 Na^+ and K^+ are transported into the Malpighian tubule so that water follows and flushes the contents of the tubule into the gut. They are transported out of the hindgut and rectum to create a concentration gradient for osmotic reabsorption of water from the gut, made possible by the precipitation of uric acid.

Figure 51.9 The blood flowing down the vasa recta always has a slightly lower osmolarity than the interstitial fluid at the same level because it is flowing and the equilibration is not instantaneous. The opposite is true for the ascending limb of the vasa recta, where the blood always has a slightly higher osmolarity than the surrounding interstitial fluid. As a result, the blood in the ascending limb absorbs water osmotically and carries some excess salt and water out of the renal medulla.

Figure 51.10 Blocking the Na^+ transport out of the thick ascending limb of the loop of Henle would result in a loss or a decrease (depending on the extent of the drug action) of the concentration gradient in the medulla. As a result, the tubular fluid in the collecting duct could not be concentrated, so urine flow would increase and there would be increased loss of water.

Figure 51.16 The vampire bat has long loops of Henle like the desert gerbil.

APPLY WHAT YOU'VE LEARNED

1. Yes, the RMT is a good predictor of the ability of a species to concentrate its urine.

2. Although several species with low percentages of long loops cannot produce highly concentrated urine, some with high percentages of long loops have only moderate capacity for producing concentrated urine and three of the species that produce the most concentrated urine have low percentages of long loops. If you calculate a correlation coefficient for these data, it is 0.44, and with a sample size of 7, the p value is 0.32, so this is not a significant correlation.

- RMT is a much better predictor of an animal's ability to produce concentrated urine. As you can see in the percent of long loops of Henle versus FPD plot, animals such as the dog, cat, and sand rat, which have 100 percent long loops of Henle, were unable to produce the high concentrations of urine seen in the kangaroo rat and jerboa. By contrast, in the RMT versus FPD plot, animals with a high RMT, such as the sand rat, kangaroo rat, and jerboa, were able to produce higher concentrated urine than animals with a lower RMT.

Chapter 52

RECAP 52.1

- Fixed action patterns are genetically determined, adaptive behaviors that are usually activated by specific stimuli normally encountered in nature. Pavlovian conditioned reflexes are physiological processes triggered by learned, non-natural stimuli. Behaviors resulting from operant conditioning are random behaviors without physiological or adaptive significance; they are activated by non-natural stimuli that the animal has learned to associate with receiving a reward when expressing the behavior.
- A genetically determined behavior might not be expressed in a deprivation experiment if the animal is not in the appropriate developmental stage or physiological condition, and if the necessary stimuli for the behavior are absent.
- Proximate causes of mating-display behavior include physiological reproductive condition and presence of stimuli from a sexually receptive conspecific. The ultimate cause of mating-display behavior is reproductive success—how many of one's offspring live and mature to contribute to the next generation.

RECAP 52.2

- If the expression of vasopressin and oxytocin genes is increased in montane voles, the voles should be more likely to form pair bonds, and both males and females should exhibit increased parental care. If that result is not observed, it could be due to the lack of receptors in the right brain areas of the montane vole.
- You would conclude that the trait is likely controlled by a single gene with a dominant and a recessive allele.
- The evolutionary advantages of having a species-specific mating behavior controlled by a gene expression cascade are that: (1) a single signal can induce a complex combination of responses necessary for that behavior, and (2) temporal coordination of all of those components is ensured.

RECAP 52.3

- If neonatal genetic male and female rats are gonadectomized, they both develop female sexual responses to estrogen as adults, and they are both unresponsive to testosterone stimulation as adults.
- The songbird will not sing its song until it reaches sexual maturity, and at that time it has to learn to sing the template it formed as a nestling. To learn, it must practice and hear itself sing. Once its song has crystalized, the bird will be able to sing it even if deafened.
- Variability in a species-specific behavior such as birdsong might be adaptive if it enables an individual to

establish identity with a different local population or to create a new song feature that enhances its attractiveness to potential mates. Variability in this same species-specific behavior could be maladaptive if it detracts from individual recognition. For example, in a situation in which an individual is returning to its nesting grounds to mate with a previously established mate or to feed offspring, it is important to be able to establish individual identity.

RECAP 52.4

1. The benefit of the marsh-nesting site is that it reduces the risk of predation. The cost is that there is greater competition for those sites and less food availability. Feeding in upland areas opens up a greater potential food source, and it does not involve the cost of defending a feeding territory. A risk, however, may be exposure to predation and the need to leave the nest unguarded during feeding.
2. The cost of being a dominant male cichlid is the energetic expenditure involved in territory defense and courtship of females. Also, there are opportunity costs in having less time to feed. The benefit is the likelihood of attracting a mate and fertilizing her eggs. The nondominant male does not incur the costs of territory defense and display and benefits from being able to achieve some reproductive success.
3. Female elephant seals have to have access to a beach to give birth and rear their young, and males can guarantee that access by excluding other males from their piece of beach. Thus the major focus of male elephant seal territorial behavior is exerting physical dominance over other males, and natural selection has optimized the males' ability to do so. Female elephant seals have no choice over who their "beachmaster" is. In contrast, female prairie-chickens do not need the territory of a male to rear their young, so they are able to simply choose the male they find most attractive. Therefore natural selection in prairie-chickens has favored male displays that are directed at females rather than at other males.
4. One source of selective pressure would be minimization of opportunity costs; therefore the amount of calories obtainable per unit of foraging time would be a critical variable. Another selective pressure is the danger of predation; the relative risk of exposure to predators in the open versus protected environment would be another critical variable.

RECAP 52.5

1. A free-running circadian rhythm is one that is not entrained to a regularly occurring signal, such as sunrise and sunset, but is expressing an endogenous periodicity. When a time cue such as a regular light-dark cycle is imposed on a free-running rhythm, that cue will either phase advance or phase delay the circadian clock to bring it into phase with the environmental light-dark cycle.
2. The direction to the sun can be used to tell compass directions if you know the time of day. A time-compensated solar compass uses an endogenous timing mechanism to compensate for the movement of the sun's position in the sky. Thus, if a honey bee finds food to the south at noon, its waggle dance on the honeycomb in the hive will be straight up, but as time passes into the afternoon, the direction of the waggle dance will have to be more and more to the left of straight-up to indicate that the direction to the food source is south.
3. The most efficient forms of inter-individual communication are tactile communication, which can be highly specific to the individual, and visual communication, which can convey considerable specific information in a very short time to an individual that is focused on the sender. Sound is an efficient form of communication for a broader population because it permeates the whole environment. Olfaction can be good for either individual or for population communication, depending on the volatility of the odorant.

RECAP 52.6

1. Selection will favor an individual helping its parents raise offspring rather than breeding itself when the chances of its own successful breeding are very low. Raising several brothers or sisters contributes more to an individual's inclusive fitness than not raising one's own offspring.
2. Because of the haplodiploid mechanism of sex determination in hymenopterans, sisters share 75 percent of their genes, but parents and offspring share only 50 percent. The unit of reproductive success in eusocial insects is the colony formed around a queen. By helping her mother raise sisters, it is likely that a worker will share 75 percent of her genes with a new queen, but if the new queen were one of her offspring, the worker would share only 50 percent of her genes.
3. The main risk of mobbing a potential predator is the possibility of being attacked and injured by the predator. A benefit of mobbing is that the predator is distracted from focusing on specific prey, such as the eggs or nestlings of the mobbers. The mobbing also warns others in the population of the presence of a predator. Of course, the major benefit is that the predator is driven away. Hypotheses about individuals taking part in mobbing would include that they are likely to be related, that they are more likely to participate if they have nestlings, and that monogamous males are more likely to join in mobbing than are promiscuous males.

WORK WITH THE DATA, [P. 1124](#)

1. If the song provides information about mate recognition, the female should show a strong preference for

- her mate's directed song over the directed song of other males.
- Standard deviations are 5.9 and 19.3. The P-value is <0.001 . Yes, the females clearly demonstrate recognition of and attraction to their mate's directed song versus the directed song of an unfamiliar male.
 - These data suggest that the directed song provides information about individual identity and plays a role in pair bonding of the male and female.
 - Undirected song may be an opportunity for the male to experiment with and practice slight variations in his song, but it may also represent a lower level of motivation to perform.

FIGURE QUESTIONS

Figure 52.2 It is unlikely that specific recognition of a complex stimulus could be genetically programmed.

Figure 52.11 The extended activity bouts of the mouse in the second panel represent the portion of the animal's circadian rhythm that corresponds to what its circadian clock is predicting as night. Therefore the light pulse in this experiment would be similar to seeing light early in the night. This is similar to what our experience would be after traveling from east to west—sunset would come later than our circadian clock would predict. In other words, we would get a light stimulus in the early portion of our circadian night. The result would be a delay of the circadian rhythm to bring it in line with the local light-dark cycle.

APPLY WHAT YOU'VE LEARNED

- When females have no larvae or old larvae that no longer need parental care, they invest their energy in producing new broods. However, during the short period when larvae are dependent on parental investment ("new larvae"), the female fertility rate is low. Thus females seem to direct their investment of time and energy into the activities most likely to result in reproductive success.
- Question 3 of Tinbergen applies. It asks about how a behavior influences survival and reproductive success, and therefore, it deals with ultimate causes of behavior. This study looked into the egg-laying behavior of female beetles under different circumstances. The results can be used to support the hypothesis that female beetles shift their energy expenditures to maximize their reproductive success. This is an ultimate cause of behavior since it deals with evolutionary pressures to maximize reproductive success.
- The data indicate a correlation between increases in juvenile hormone and suppression of egg-laying behavior. The data also indicate a correlation between increases in methyl geranate and suppression of copulation behavior. These correlations suggest that hormone and pheromone changes may be underlying physiological mechanisms that influence the shift in egg-laying behavior and sexual behavior to parental care behavior in burying beetles.
- Tinbergen's question about immediate causation 1 applies, and it deals with proximate causes of behavior. The studies were aimed at elucidating the underlying biological mechanisms that produce the observed changes in behaviors. The results can be used to support the hypothesis that expression of different behaviors comes about as the result of changing levels of hormones and pheromones produced by the female. This is a proximate cause of behavior since it deals with an immediate physiological mechanism that determines how an individual is behaving at a particular time.
- A cost of the parental care behavior is the opportunity lost for mating and egg laying that could be done instead of caring for young larvae. This means that there are times when the beetles do not actively reproduce, and so fewer offspring are produced over time. A benefit is the protection and nurturing of

young larvae, which improves the likelihood that they will survive to carry on the next generation.

Chapter 53

RECAP 53.1

1. Ecology is the study of the interrelationships among organisms and the physical environment, while environmentalism is the use of that ecological knowledge (as well as social and ethical concerns) to inform personal and public policy related to stewardship of the natural world. Ecology is a useful scientific enterprise because it can allow us to better anticipate how our actions may have negative consequences for ourselves and the natural world.
2. You could conduct observational surveys in the field to look for disease prevalence in live and dead sea stars. If multiple individuals were surveyed at multiple sites, then you might be able to make inferences of the prevalence of the disease at population and metapopulation scales. You could conduct an experiment in which you expose sea stars to the suspected pathogen to determine if they contract and die from the disease. Finally, you could create a population model to simulate how death from the disease would affect the populations of sea stars and compare the results with your observational data.

RECAP 53.2

1. No. A month of extremely hot weather does not necessarily tell us that Earth's climate is warming. Climate is the long-term average of atmospheric conditions over years to millennia.
2. Because Earth is a sphere, the intensity of solar radiation hitting its surface varies with latitude. At high latitudes, incoming solar energy comes in at an angle and has to travel through more of the atmosphere than at the equator, making it less intense than at the equator, where sunlight strikes the surface perpendicularly. The consequence of this latitudinal variation in energy input is a major difference in temperature and precipitation at every 30° latitude. At the equator, climate is tropical with warm and wet conditions. At 30° N and S, climate is warm and dry, producing desert conditions. At 60° N and S, climate is temperate with cold and wet conditions. At the poles, climate is cold and dry.
3. If you were sailing from New York to the United Kingdom (west to east), you would want to use the Westerlies and the Gulf Stream to your advantage. Thus you would want to sail in a northeastern direction across the Atlantic Ocean. If you were sailing from San Francisco to Japan, you would want to take advantage of the NE Trade Winds and the North Equatorial Current in the Pacific Ocean.
4. Earth's axis is tilted, changing the amount of sunlight a particular region receives over the course of a year as Earth orbits the sun. When the Northern Hemisphere is tilted toward the sun, it experiences summer conditions, but that means that the Southern Hemisphere is tilted away from the sun and experiences winter conditions.

RECAP 53.3

1. Mountain ranges and valleys can create local and regional differences in temperature and precipitation due to their effects on atmospheric circulation. They also influence the flow of fresh water in rivers and lakes. The topography of the seafloor creates variations in water depth, which affects light penetration, water temperature, water pressure, and water movement (i.e., currents, waves, and tides). These changes in physical conditions create different zones containing characteristic biota, which are similar to terrestrial biomes on land.
2. Cities are warmer because concrete, asphalt, and the dark roofs of buildings absorb heat from solar radiation and radiate that heat in the evening hours. Cities also produce more heat through the burning of fossil fuels from cars, factories, and buildings. The temperature differential between cities and the surrounding countryside can create "country breezes," air movement generated as rising warm air from the city is replaced by cold surface air from surrounding rural areas. Parks can serve to cool the surrounding air through the evapotranspiration of trees and other vegetation.

Year	Age (x)	Number of female birds (N_x)	Number of female offspring (N_x offspring)	Survivorship (l_x)	Fecundity (m_x)	Net reproductive rate ($l_x m_x$)	Generation time ($\sum x l_x m_x$)
2012	0	100	0	0	0	0	0
2013	1	50	75	0.50	1.50	0.75	0.75
2014	2	40	80	0.40	2.00	0.80	1.60
2015	3	30	60	0.30	2.00	0.60	1.80
						$R_0 = 2.15$	4.15

RECAP 53.4

1. Biomes are characterized using information about the growth forms of their dominant plants, which reflect the evolution of those plants under annual patterns of temperature and precipitation. Tropical rainforests

are found in equatorial regions where conditions are consistently wet and warm. The dominant vegetation is tropical trees, with up to 500 species per square kilometer. Temperate evergreen forests, by contrast, grow at middle to high latitudes, where winters are mild and wet and summers are cool and dry. The dominant trees are a handful of conifer species. The two forest types are similar in that they thrive under wet conditions and do not lose their leaves or needles on a seasonal basis.

2. Wallace saw dramatically different terrestrial species inhabiting the adjacent islands of Bali and Lombok, even though they were separated by 24 kilometers and had similar physical environments. This observation led him to hypothesize that different biota had been separated by a barrier (in this case, a deep channel), which kept them apart over evolutionary time. Wallace surmised that biogeographic regions are the result of the isolation that species experienced by residing on different continents or islands.
3. The fact that ice sheets extended into temperate regions, where species diversity is currently lower than in the tropics, better supports the species diversification time hypothesis. This hypothesis proposes that the amount of time in which speciation has taken place is greater in the tropics, where severe climate conditions did not slow down speciation or increase extinction. Thus the tropics have accumulated more species over time simply because of the lack of dramatic changes in climate.

RECAP 53.5

1. The premise of island biogeography is that the number of species on an island represents a balance between the immigration rate and the extinction rate. A faraway island will have fewer immigrants than an island close to the species pool. In addition, a smaller island will have fewer resources, and thus sustain fewer species and have higher extinction rates. Larger islands provide greater resources and can sustain larger populations (which tend to have lower extinction rates than small populations).
2. Habitat fragmentation essentially creates isolated islands of habitat surrounded by unsuitable habitat. The smaller and more isolated the habitat fragment, the fewer species that can be supported within the habitat and the less likely it is that species can move to more suitable fragments. In addition, the fragment can be exposed to edge effects--hazards outside the habitat fragment that effectively reduce its size. Leaving habitat fragments that are large enough to sustain species can reduce the effects of habitat fragmentation or by creating corridors that species can use to move safely from one fragment to another.

WORK WITH THE DATA, P. 1164

Yes, there is a positive relationship between number of bird species and size of the fragment area.

3. The scaling factor shows that to increase the t_{50} (i.e., the time it takes fragments to lose half their species) by 10-fold, the fragment area would need to increase 1,000-fold. Thus, if t_{50} for 1 hectare = 5 years, the fragment would need to be 1,000 hectares to ensure that half the species would remain after 50 years. The fragment would need to be 10,000 hectares to ensure that half the species would remain after 100 years.
4. Yes, because the average area would need to be 10,000 hectares to ensure that half the species would remain after 100 years.

FIGURE QUESTIONS

Figure 53.2 An increase in greenhouse gases increases the flux of infrared radiation back to Earth's surface and has a warming effect on climate.

Figure 53.9 Temperature inversions occur when there are large temperature extremes that produce afternoon heat and morning cold. A valley concentrates heat from the sun during the day, and as the heat rises, it forms a layer of warm air (an inversion layer). The inversion layer traps cold, dense, and moisture-laden air that then descends into the valley overnight, producing fog.

Upwelling occurs when prevailing winds blow parallel to the coastline, displacing surface water away from

the shoreline and thus allowing deep, cold water to rise to the surface. This cold water can cool moist air on the coast, creating morning fog.

Figure 53.12 All the species that are limited to a region are part of the regional species pool. Thus the regional species pool can influence species diversity and composition from the regional to local scales.

Figure 53.13 The northern hemisphere has more biome types. This is likely a consequence of the northern hemisphere having much more land area than the southern hemisphere, creating the opportunity for a diversity of temperature and rainfall regimes.

Figure 53.14 One would expect speciation to increase as land masses separated because species would become reproductively isolated from one another, thus increasing the chance that they could follow different evolutionary trajectories. The separation of species in this way is known as vicariance.

APPLY WHAT YOU'VE LEARNED

1. According to Figure B, the ability of reef fish species to respond to loss of corals is inversely proportional to the number of coral species present. The results show that fish from more diverse areas (PNG) were more sensitive to changes in the number of coral species than were fish from lower diversity areas (GBR, FP). This tendency for fish species to decline under lower coral diversity situations is a consequence of the fact that more diverse reefs contain more specialized fish species (species that depend for food and/or shelter on one or a very few coral species). These results suggest that if managers want to protect the most fish species possible, they should focus their efforts on the most diverse coral reefs where these specializations occur.
2. The PNG and GBR sites are relatively close together. Thus it would be easier for organisms, such as fish and coral larvae, to move between and colonize these sites. These colonization events could serve to increase species diversity at each site. The FP site is very isolated, and the probability of new species from the other sites reaching this area is much lower.
3. The PNG site is very near the equator, so it has a warm, stable environment. One theory that could explain species diversity as it relates to latitude is the species diversification time hypothesis. Equatorial species have had a very long time to evolve, unaffected by conditions (such as glaciation) that caused extinctions at higher latitudes. The other sites are slightly farther from the equator, which might make them slightly less likely to reach high levels of diversity. Another explanation might be the theory of island biogeography and the related concept of species-area relationship. That is, higher species diversity is associated with greater land area, and isolated islands will show decreasing numbers of species with increasing distance from a source of new species. Although both PNG and GBR are islands, both sites are close to other islands and to a large landmass (Australia), making them likely to be colonized by species from these areas. The FP site is much more isolated and therefore much less likely to be colonized.
4. As climate change progresses, coral reefs are likely to degrade and show local extinctions of coral species. The experiment shows that reefs with higher coral diversity are likely to have greater declines in fish species number as well. Thus, if climate change continues on its present course and coral reefs continue to decline in the future, the reefs that remain will likely have lower fish species diversity. Because areas with high coral diversity have more specialized fish species, these species will be most at risk. PNG—and to a lesser extent GBR—will likely lose specialized fish species. FP, which is more isolated and has a lower coral diversity, will likely lose fewer (or no) fish species.

Chapter 54

RECAP 54.1

1.

Yes, the five populations of humpback whales make up one metapopulation on their summer feeding grounds. All populations except the yellow and blue populations overlap in their summer feeding areas and thus have the potential to exchange individuals. The yellow and blue populations overlap with the other three populations, however, so they are still part of the metapopulation.

2. Intraspecific competition for food resources is likely responsible for fluctuations in the aphid population size over time. Aphid populations undergo boom-and-bust cycles triggered by their population densities. Predation keeps these fluctuations in check by controlling the density of aphids before they reach boom-and-bust conditions.
3. Approaches used to estimate population sizes include full censuses, surveys using quadrats or transects, mark-recapture methods, and DNA analyses.
4. The most appropriate method would probably be mark-recapture. Quadrats and transects are appropriate only for plants and sessile animals. In a large area, or in water, it is impractical or impossible to do a full census. For animals that can move, the best approach is to collect a sample of animals, mark them, and then recapture them and count the marked organisms. This allows the researcher to calculate a reasonable estimate of the population.

RECAP 54.2

1. $N_t = N_0 + (B - D) + (I - E)$

N_t = population size at time t ; N_0 = population size at time 0; B = number of individuals born between time 0 and time t ; D = number of individuals that died between time 0 and time t ; I = number of individuals that immigrated between time 0 and time t ; E = number of individuals that emigrated between time 0 and time t .

2.

Year	Age (x)	Number of female birds (N_x)	Number of female offspring (N_x offspring)	Survivorship (l_x)	Fecundity (m_x)	Net reproductive rate ($l_x m_x$)	Generation time ($x l_x m_x$)
2012	0	100	0	0	0	0	0
2013	1	50	75	0.50	1.50	0.75	0.75
2014	2	40	80	0.40	2.00	0.80	1.60
2015	3	30	60	0.30	2.00	0.60	1.80
						$R_0 = 2.15$	4.15

- a. $R_0 = 2.15$; $G = 4.15/2.15 = 1.93$; $r = \ln(2.15)/1.93 = 0.40$.
- b. $N_t = (120) e^{-0.40 \times 20} = (120)(2,982) = 357,720$.
- c. $N_t = 300/(1 + [(300 - 120)/120] e^{-0.40 \times 20}) = 300/1.0005 = 300$.

3.

This cohort has a type II survivorship curve, which is typical for birds, fish, and plants.

4. Density-dependent factors controlling this cohort could include limiting resources that decrease population growth under high densities as a result of intraspecific competition; and predators or pathogens that can have a differential effect on the mortality of individuals in high population densities. Density-independent factors controlling this cohort could include extreme cold or an exceptionally strong hurricane that kills a large number of individuals in the population.

RECAP 54.3

- 1a. Life expectancy has increased steadily over the past 175 years, suggesting that advances in food and health security (i.e., environmental factors) have allowed humans to live longer. Changes in genetically determined life span would occur over evolutionary time.

- b. The differences in life span for citizens of Japan versus Angola are also mostly the result of environmental factors. Citizens of Japan generally have a better quality of life than those of Angola, due to Angola's high rates of HIV infection and civil unrest.
2. There are life history trade-offs because constraints on optimality include genetic variation for evolution to act on as well as the mediating effects of the physical and biological environments. Examples of trade-offs are allocation of resources, high growth versus high reproduction, and high reproduction versus survival.
3. *Lobelia telekii* reproduces just once, produces many seeds, and has a short life span, which falls on the side of an *r*-strategist. *L. keniensis* reproduces multiple times, produces fewer but larger seeds, and lives longer, suggesting a *K*-strategist life history. In terms of the guppy example, those living in high-predation streams have an *r*-strategist life history whereas those living in low-predation streams have a more *K*-strategist life history.

RECAP 54.4

1. Species that have a *K*-strategist life history live longer, reproduce at a larger size, and produce fewer offspring over a longer period of time compared to *r*-strategists. As a result, recovery may require managing the number or size of the individuals within the population so that they live long enough, and/or reach a large enough size, to successfully reproduce at a rate that increases their population size over time.
- 2a. Some factors that affect the metapopulation size of the Edith's checkerspot butterfly in the San Francisco Bay area include the number and size of serpentine rock outcrops with the host plants of the butterfly, the effects of climate on the populations, the dispersal rates between the populations, and the number of source and sink populations.
- b. With the extinction of the Morgan Hill population, the metapopulation faces likely extinction. Large populations, such as Morgan Hill, serve as sources that recolonize smaller populations after temporary local extinctions. Without such source populations, continuation of the metapopulation over the long term is much less likely.

WORK WITH THE DATA, P. 1171

1. The equation in [Figure 54.5A](#) states that $N = (n \times n_2)/M$. In words, the estimated total number of ticks (population size N) equals the total number of individuals captured, marked, and released in the first sample ($n = 180$) times the total number of individuals captured in the second sample ($n_2 = 33$) divided by the number of marked individuals recaptured in the second sample ($M = 8$). Thus N (estimated population of the sampled lawn) = $(180 \times 33)/8 = 5,940/8 = 742.5$ adult ticks.
2. Calculate this by dividing 742.5 (the estimated number of ticks in the lawn population, per Question 1) by 700 (number of m^2) = approximately 1.06 ticks per square meter.
3. This study was conducted in order to evaluate the risk that residents of this suburban neighborhood have of encountering the tick vectors of Lyme disease in their own yards; a high risk of encounter means that there is also likely to be a high risk of contracting the disease. A density of slightly more than one tick per square meter of lawn suggests that residents of this community are indeed likely to encounter ticks and, accordingly, have a high probability of contracting Lyme disease if they spend time outdoors on their lawns.

WORK WITH THE DATA, P. 1174

1. $N_t = (7.4 \text{ billion})e^{0.0118 \times 85} = (7.4)(2.73) = 20.2 \text{ billion}$.
2. $N_t = (10 \text{ billion})e^{0.005 \times 20} = (10)(1.01) = 10.1 \text{ billion}$.
3. 2015 data: $N_t = s_{12} / [1 + ([12 - 7.4]/12)e^{-0.0118 \times 85}] = 12/1.14 = 10.5 \text{ billion}$.
2080 data: $N_t = 12 / [1 + ([12 - 10]/12)e^{-0.005 \times 20}] = 12/1.15 = 10.4 \text{ billion}$.
4. Reducing the population growth rate will reduce the population size by 2100 slightly more than reducing the carrying capacity will. But either parameter would be important to reduce population size.

FIGURE QUESTIONS

[Figure 54.6](#) The blue curve ($r = 1$) has a faster growth rate, and thus a steeper slope, than the red curve ($r = 0.25$).

[Figure 54.8](#) Exponential growth occurs when the rate of change in population size is multiplicative but constant over time. Logistic growth occurs when resources are limited and intraspecific competition slows growth of the population to its maximum size (carrying capacity).

[Figure 54.9](#) Humans have a type I survivorship because they have high overall survivorship through adulthood but a steep decline later in life. Species with this type of survivorship curve typically have low reproduction rates but provide parental care to their offspring, which reduces the risk of death in early stages of development.

[Figure 54.12](#) Yes, the life history strategies of the guppy populations are likely genetically determined.

When the two populations were provided with unlimited food and lacked exposure to predation, they did not change their strategies.

Figure 54.14 Yes, the rate of change is predicted to increase. From 1840 to 1940, female life expectancy increased by 25 years (from 45 years in 1840 to 70 years in 1940), thus the rate of change is 55% $((25/45) \times 100\%)$ over 100 years. From 1940 to 2040, female life expectancy is predicted to increase by 25 years (from 70 years in 1940 to 95 years in 2040), thus the rate of change is 36% $((25/70) \times 100\%)$ over 100 years. So over the same amount of time (100 years), life expectancy increased faster in the first time interval (1840-1940) than it is predicted to do in the second time interval (1940-2040).

APPLY WHAT YOU'VE LEARNED

- Individual age values are shown in the table below. They are calculated by multiplying l_x by m_x for each age class. The net reproductive rate for the population is calculated as $R_0 = \sum (l_x m_x)$, or $0 + 0.63 + 0.49 + 0.31 + 0.17 + 0.09 + 0.06 + 0.03 + 0.02 + 0.01 + 0 = 1.81$. This represents the mean number of offspring produced by each reproductive individual in the cohort during her lifetime.

Age (x)	0	1	2	3	4	5	6	7	8	9	10
$x l_x m_x$	0	0.63	0.49	0.31	0.17	0.09	0.06	0.03	0.02	0.01	0

- The population is increasing. Because the life table adjusts for deaths at each year in the life cycle, death rates are built into the life table. If the value of R_0 is greater than 1 (as this one is), the population is increasing.
- The generation time is calculated by first multiplying the age class (x) by the reproductive rate for that age class ($l_x m_x$) to get $x l_x m_x$. The values are summed as $G = \sum (x l_x m_x)$, or $0 + 0.63 + 0.98 + 0.93 + 0.68 + 0.45 + 0.36 + 0.21 + 0.16 + 0.09 + 0 = 4.49$.

Age (x)	0	1	2	3	4	5	6	7	8	9	10
$x l_x m_x$	0	0.63	0.98	0.93	0.68	0.45	0.36	0.21	0.16	0.09	0

- The per capita rate of increase is calculated as $r = (\ln R_0)/G$. Thus $r = (\ln 1.81)/4.49 = 0.132$.
- Sharpnose shark populations are more likely to have a higher r value than are populations of temperate sharks. Sharpnose sharks mature and reproduce early, so they produce offspring more rapidly than larger sharks, even though they have a shorter life span. Also, sharpnose sharks are small and not deliberately fished but are part of bycatch. Larger, temperate species, because of their slow growth, late maturity, and limited offspring, reproduce more slowly. If fishing pressure becomes intense, temperate sharks could be overfished.

Chapter 55

RECAP 55.1

- (a) Mutualism (b) Amensalism (c) Parasitism (d) Competition
- The conditions that can modify or change a two species interaction include physical conditions, biological processes such as dispersal, and other interacting species.
- No, it is unlikely that the lionfish prey in the Atlantic have had enough time to adjust in an evolutionary way to their novel predator. This conclusion is supported by the data, which show that some reefs in the Atlantic have suffered a 65 percent decline in small-bodied coral-reef fish.

RECAP 55.2

- Perhaps the simplest behavior a reef fish might adopt—or that might evolve in reef fish—would be to avoid headfirst capture by the lionfish. This might involve adopting a way to detect a lionfish's presence and fleeing the encounter before the predator could use jets to create a headfirst capture. Or after being hit by a jet of water, the prey could adopt unpredictable swimming movements to avoid headfirst capture.
- Both herbivory and parasitism typically involve a symbiosis in which the herbivore or parasite is smaller than, and may live on, the plant or host. This close relationship naturally leads to species evolving specialized mechanisms that counter their effects on one another. In addition, the prey of herbivores are plants, which are immobile, and thus may also evolve special mechanisms in response to the potential for intense herbivory.
- The number of grass species would be highest when the hare population is highest and lowest when the hare population is lowest.

RECAP 55.3

- A realized niche is defined by a species' interactions with other species. The red squirrel's realized niche has become smaller because of the competition with the gray squirrel.
- Herbivory by the hares is the interaction that allows the grass species to coexist with one another. By

grazing on the dominant grass species, the hares allow more subordinate grass species to thrive.

3. Scenario 1 is an example of exploitation competition because you and your friend are sharing the milkshake resource. Scenario 2 is an example of interference competition because your friend is excluding you from the milkshake resource

RECAP 55.4

1. An obligate mutualism would evolve when the two species involved in the interaction benefit from each other more than from other partners. A facultative mutualism would evolve when the two species involved in the interaction benefit from partnerships with multiple species. For example, if multiple species can deliver pollen or seeds to their desired locations, then facultative relationships will be more likely to evolve.
2. Both species of barnacles are more likely to benefit from positive interactions under the more stressful conditions of the high intertidal where desiccation occurs.
3. Examples include trees, coral reefs, and kelp forests, where the habitat provided by these species facilitates many other species that depend on them.

WORK WITH THE DATA, P. 1193

1. The researchers used both methods to collect data for two different purposes. In the open aquarium trials, they wanted to observe the behavior of the lionfish and its prey in a relatively natural setting to see what strategies the lionfish used to capture and eat the prey. They learned that the lionfish would capture the prey when the prey turned and oriented its head toward the head of the lionfish. This headfirst orientation allowed the lionfish to more easily capture its prey.
In the container trials, the researchers wanted to observe the behavior of the lionfish, particularly the production of water-jet pulses from its mouth, in a setting where the lionfish could see, but not capture or eat, the prey. In this way the researchers could measure the number of water jets produced and the maximum distance a water jet could travel, to get an idea of what behaviors a lionfish might employ when its prey was hard to catch (in this case, because the prey was in an inaccessible container).
2. Given that fish prey in the Atlantic Ocean are more naive to lionfish predatory behavior than fish prey in the Pacific Ocean, it would make sense that lionfishes would need to produce fewer and closer jets of water to capture their fish prey in the Atlantic Ocean compared with the Pacific Ocean. The Pacific Ocean fish should be harder to catch and thus require more water jets produced from a greater distance from the prey.
3. The field observations suggest that Pacific Ocean lionfishes need to resort to the water jet-blowing behavior to catch their prey more often than Atlantic Ocean lionfishes do. This pattern could be explained by the hypothesis that fish prey in the Atlantic Ocean are more naive to lionfishes and thus easier to catch. Atlantic Ocean fish prey are less likely to take appropriate evasive actions or require the use of the water jet-blowing behavior to confuse or disorient them. In addition, it is likely that the production of water jets is metabolically costly, and that lionfishes would use this behavior only when the cost of producing it is outweighed by the advantages it confers. Presumably this would be more likely to be the case for prey in the Pacific Ocean than for prey in the Atlantic Ocean.

FIGURE QUESTIONS

Figure 55.1 Yes. In the buffalo photo, trophic interactions include parasitism by the ticks, predation by the birds both of ticks on the buffalo and insects in the grass, and herbivory by the buffalo. Symbioses include the parasitic ticks on the buffalo. In the wolf and bear photo, the wolves are involved in a trophic interaction.

Figure 55.2

Effects of species 1 on species 2

Effects of species 2 on species 1

Figure 55.9 The peak number of lynx usually occurs after the peak number of hares. One reason this might occur is that as hare abundance rises, lynx have more prey and thus can produce more offspring. However, these offspring are not born immediately, so the rise in lynx numbers lags behind the rise in hare numbers.

Figure 55.11 If both *P. caudatum* and *P. bursaria* fed on yeast, one of the species would likely become extinct.

APPLY WHAT YOU'VE LEARNED

1. Pollination is a positive interaction, or facilitation. Specifically, it is a mutualism, meaning both partners benefit. Bees obtain food (pollen and nectar) from plants. Plants rely on bees for pollination, which is necessary for successful reproduction. For a successful pollination interaction, bees must emerge at the same time that plants flower.
2. Over time, the trend in bee pollination date is slightly downward, indicating that the bees were pollinating slightly earlier in the year. The mean April temperature showed an upward trend, indicating that temperatures rose over the time period. The opposing directions of the trends indicate that as temperatures rose, bees were pollinating earlier in the year. The steeper slope after 1970 on both graphs suggests that temperature has increased faster since 1970. Statistical analysis bears this out; 69 percent of the bees' advance in pollination activity has occurred since 1970.
3. The recent study (1971-1999) shows plant flowering advancing faster than bee pollination dates, and thus best supports the hypothesis that climate warming is affecting plant-pollinator interactions by creating mismatches in the timing of these events.
4. Specialist plant-pollinator interactions are more likely to be affected by timing mismatches caused by rising temperatures. Generalist species (such as those in these studies) can rely on many species for food or pollination interactions; if one or several species pairs show timing mismatches, other species will likely be present to participate in the interaction. Specialist pairs, which depend on only one or a few species, are far more susceptible to the effects of timing mismatches. If timing mismatches occur, there may be no species available to interact with.
5. There are many possible designs, but more precise information would require analysis of specific plant-pollinator pairs, rather than the generalized groups in the current studies. The study would require seasonal measurements of plant flowering dates and pollinator emergence and pollination activity dates (as opposed to collection dates) for several years, correlated directly with climate data. Ideally studies should focus on pairs for which background information is already available on past emergence and flowering dates. Good candidates would include pollinators of important crop plants, such as apple trees or tomatoes.

Chapter 56

RECAP 56.1

1. Subsets of species are used to describe communities because it is impractical to account for every species in a community. There are at least two reasons for this: (1) communities can vary in spatial and temporal scale, making it hard to designate boundaries around them, and (2) it is impossible to identify every species in a community because many are not described. For example, many bacteria, small microbes, and small invertebrates are hard to see, let alone identify.

The community subset used for frogs and toads on Mount St. Helens was a taxonomic one—they all belong to an amphibian community.

2. Nontrophic interactions, such as competition and facilitation, are not depicted in the food web.

3. Pond A

	Abundance	Proportion (p_i)	$\ln(p)$	$P_i \ln(p_i)$
Pacific tree frog	6	0.3	-1.20	-0.36
Western toad	8	0.4	-0.92	-0.37
Northern red-legged frog	4	0.2	-1.61	-0.32
Cascades frog	2	0.1	-2.30	-0.23
H				1.28

The new Shannon index value for pond A is $H = 1.28$. Pond B, with $H = 1.39$, still has slightly higher species diversity than Pond A.

RECAP 56.2

1. The most important factor limiting species membership in the local community is dispersal and immigration. Seven species did not pass through the species supply filter, while 4 species and 3 species, respectively, did not pass through the abiotic and biotic filters.
2. Given that the species supply filter has the most potential to exclude species from a local community, the best management action would be to exclude, as much as possible, non-native species from entering the mountain in the first place.

RECAP 56.3

1. Elk would be released from the direct interaction of predation by wolves and would increase in abundance. The increase in elk would result in more grazing pressure on aspens, causing them to decline. Thus, fewer wolves would have indirect effects for aspen. With fewer aspens, there would be other indirect effects of the lack of wolf predation: fewer snowshoe hare, beaver, and other rodents that depend on aspens for food. Fewer small herbivores could affect other carnivores in the system such as coyote, raven, and short-tailed weasels.
2. Beavers most closely fit the ecosystem engineering species definition because they are able to create, modify, and/or maintain physical habitat by cutting down (and killing) trees and using them to dam streams and create ponds and wetlands that provide habitat for themselves and other species. Beavers might also be considered a keystone species because their effect is large relative to their size or abundance, but keystone species are thought to mostly act through food webs by creating trophic cascades. Beavers would not be considered foundation species because foundation species have large effects on the communities as a consequence of their large size or great abundance.
3. The lottery model poses that in communities where species use similar limiting resources and have similar effects on one another, the element of equal chance for all individuals to obtain those resources determines coexistence. The model assumes that when resources are made available, they are used at random by individuals of different species that happen to be in the “right place at the right time.” As long as all individuals have similar chances of obtaining resources (or “winning the lottery”) and no clear advantage in population growth, then their presence in the community should be maintained by chance events that free up resources for individuals competing for those resources.

RECAP 56.4

1. Disturbance is an abiotic event that may physically or chemically injure or even kill some individuals, creating opportunities for other individuals to grow and/or reproduce. For example, hurricanes, forest fires, and volcanic eruptions are disturbances. Stress occurs when some abiotic factor reduces the growth, reproduction, and ultimately survival of some individuals. For example, drought or extreme cold can cause stress in organisms.
2. Some biotic factors that induce change in communities include species interactions, such as predation, competition, or disease. Others include physical damage by organisms, such as trampling or digging.
3. False. Primary succession is controlled by facilitative and inhibitory processes acting together over time. The progress of succession depends on the early colonists, each of which can facilitate and inhibit other colonizing species. For example, in Glacier Bay *Dryas* and alders allowed spruce trees to become established, but later in succession, competition from spruce trees led to the decline of early successional species.
4. An alternative state, or regime shift, occurs when a disturbance or stress causes a community to follow a different successional trajectory, leading to an alternative community state. Examples include the extirpation and then reintroduction of wolves to aspen forests of Yellowstone National Park, the presence or absence of sea otters in kelp forests along the west coast of North America, and the effects of beavers on wetlands in Minnesota.

RECAP 56.5

1. Costa Rican farmers often grow multiple crops together (such as corn and sweet potatoes) to reduce the number of insect pests that attack the plants. For example, parasitoid wasps are attracted to corn pollen and attack sweet potato pests, thus benefitting the sweet potato crop. Likewise, the corn plants receive pollination services from the wasps.

Growing polycultures could be a good strategy under drought conditions if each species performs differently under low water conditions. For example, if one species performs better than another, overall productivity could still be high compared with a condition in which only one species, or monoculture, that did not respond favorably to drought.

<i>H</i>			0			1.68			1.44			1.04

The Pumice Plain had the lowest species diversity ($H = 0$) and the Blowdown Zone had the highest species diversity ($H = 1.68$). The Pumice Plain had the lowest species richness (1 species) compared to the Blowdown Zone, which had the highest species richness (7 species). The Reference and the Tephra-fall Zone both had the same species richness (6 species).

2.

The species diversity data for small mammals seem to fit the intermediate disturbance hypothesis well. As the degree of disturbance experienced by the four community types increases, so does species diversity of small mammals in those communities, up to a point—the Blowdown Zone. Species diversity then declines under the extreme conditions of the Pumice Plain.

The pattern of species diversity seen in small mammals in the Tephra-fall and Blowdown Zones could be determined by the variety of different habitats and resources that became available to them in the secondary successional communities that developed after the eruption. Compared with the reference area, these two communities likely foster more species and at a higher relative abundance because of these new resources. In the primary successional community of the Pumice Plain, though, the habitats

and resources are not nearly as diverse or abundant and thus cannot support more than one small species.

3. The deer mouse (*Peromyscus maniculatus*) is the only species present in all four communities. This suggests that the deer mouse has a life history that allows it to live in primary, secondary, and climax successional communities. It is likely able to disperse widely, grow quickly, and reproduce often—all characteristics of an early successional, r-strategist species. The deer mouse is also likely to be an opportunistic and generalist species, living in a variety of habitats and feeding on a variety of food items.
4. The Tephra-fall and reference area communities have more species in common than the Blowdown Zone, but all three communities have their own characteristic small mammal species assemblages. Given that each community is represented by a different successional stage, with vegetation characteristic of secondary and climax successional communities, it makes sense that the species composition of the small mammals inhabiting those communities will reflect these differences.

FIGURE QUESTIONS

Figure 56.4 Pond B has higher species diversity ($H = 1.388$) than Pond A ($H = 0.589$), because even though both ponds have the same species richness, Pond B has greater species evenness.

Figure 56.6 No, they would not be found in the local community depicted in the figure. The species in the local community are all terrestrial species, and thus fish and frogs, which are aquatic, would be excluded from the community by the abiotic filter.

Figure 56.15 The oldest communities are located in the areas that have been exposed the longest since glacial retreat, such as the mouth of the bay, where succession has proceeded for 200 years. As the glaciers melt and retreat up the bay, the communities become younger and younger, with the youngest pioneer community closest to the glacial front.

Figure 56.16 Pocket gophers most closely fit the ecosystem engineering species definition because they are able to create, modify, and/or maintain physical habitat for themselves and other species through their burrowing activities. They might also be considered a keystone species because their effect is large relative to their size and abundance. However, keystone species are thought to act mostly through food webs by creating trophic cascades.

APPLY WHAT YOU'VE LEARNED

1. Corals are foundation species because their effects on the coral-reef community are due to their relatively large size and abundance. They are also ecosystem engineering species; as they grow, their skeletons physically modify the environment, increasing habitat for other reef species.
2. The genera *Acropora* and *Orbicella* would be most important in building reef structure, and *Porites* and *Agaricia* would be least important. *Acropora* and *Orbicella* have the highest rugosity, indicating greater complexity, which results in a diversity of reef habitats. They also have the highest calcification rates, indicating that they add reef structure more rapidly than the other two genera.
3. Because of the rapid decline in both reef rugosity and rate of calcification, the genera *Acropora* and *Orbicella* are likely declining most rapidly. These are the genera most responsible for the large size and complexity of the reef. The loss of these genera would affect reef function by reducing the number of habitats and thus the number and abundance of many species in the reef community.
4. The reef does not appear to be regaining its original functionality, at least in the time span of the model. Although the coral cover increases from 10 to 45 percent, neither rugosity nor calcification rate shows a corresponding increase. Rugosity varies only slightly over the time span, ending with a slight upward trend. Calcification rate increases near the middle of the time period before showing a continuous downward trend. The low levels of both factors, compared with their very high levels in the original healthy reef (seen at the start of model i), indicate a much lower functionality. The low functionality may be a matter of timing; a reef's function can be compromised when foundation species are lost (as shown in model i), but because the foundation species (massive corals such as *Acropora* and *Orbicella*) are replaced slowly, it takes much longer for the reef to recover. The lower functionality probably indicates that foundation species are being replaced by smaller species such as *Porites* and *Agaricia*, both of which have lower rugosity and calcification rates. Their effect may be significant in the short term because of their rapid reproductive rate, but less than that of *Acropora* and *Orbicella* because they do not contribute significantly to reef building.
5. Yes, both model coral-reef communities are undergoing succession. For model ii, the recovery could be considered secondary succession, given that it is restoring its structure after a major disturbance (loss of most of its coral structure). According to the concept of alternative states, under similar environmental conditions, succession can result in different assemblages of organisms. That is, the new community does not return to its original state. In model ii, the coral community does not reach the same level of rugosity or calcification as the starting conditions of model i, indicating that either different species are present and/or their abundance has changed. The lower levels of rugosity and calcification will result in fewer habitats and lower biodiversity. Given more time, as the reef continues to undergo succession,

more massive, slower-growing corals may again predominate, and the reef may be able to support higher species diversity. But the possibility that the coral-reef communities show hysteresis, or the inability to recover to the original community, is also a possibility if the effects of climate change intervene.

Chapter 57

RECAP 57.1

1. Not necessarily. Ecosystem science is the study of how energy flows and nutrients cycle through the biotic and abiotic environment. The number of species is a descriptor of the biotic environment but does not give any information about the energy flow or nutrient cycling of the ecosystem.
2. Energy and carbon can be converted into primary production through photosynthesis and chemosynthesis. Photosynthesis involves the capture of radiant energy by plants, algae, and photosynthetic bacteria to be used to fix CO₂ into organic compounds. Chemosynthesis involves the capture of energy from inorganic compounds by archaea and bacteria to be used to fix CO₂ into organic compounds. Chemosynthesis typically occurs in ecosystems such as hydrothermal vents, hot springs, and soils that lack sunlight and have high concentrations of particular inorganic compounds.

RECAP 57.2

1. The open ocean has very low average net primary productivity (~100 g/m²/yr), compared with algal beds and coral reefs (2,500 g/m²/yr). However, because there is so much more open ocean (nearly 70% of Earth's surface) than there are algal beds and coral reefs (only 0.1% of Earth's surface), open ocean accounts for a much higher percent of Earth's NPP.
2. No, primary producers will not be able to lower global CO₂ appreciably. CO₂-enrichment experiments show that primary producers can increase their NPP under increased CO₂ concentration, but there is a limit. That limit is set by other factors, such as nutrients, light, and water. In addition, the effects may be somewhat counteracted by respiration of CO₂ by consumers feeding on primary producers.
3. Eutrophication can, but does not always, result in the explosive growth of algae, which can severely deplete oxygen (hypoxia) when they decompose. The level of hypoxia is driven by the amount of algae subject to decomposition and the level of oxygen available in the system.

RECAP 57.3

1. The lake food web would have the higher trophic efficiency. Forest ecosystems have lower trophic efficiency than aquatic systems because much of the NPP in forests is in the form of wood and is unavailable to consumers. In contrast, the lake food web is based on phytoplankton and algae, which are more easily converted to secondary production. Estimates suggest that, on average, only 13 percent of terrestrial biomass is consumed by herbivores, compared with 35 percent in aquatic ecosystems. The crayfish, which is an ectotherm, would have a higher trophic efficiency than the bear, which is an endotherm. Endotherms maintain higher metabolic rates than ectotherms and thus have less energy left over to devote to growth and reproduction.
2. The lake with three trophic levels would have the higher NPP. A three-level food web in which the top carnivore affects an herbivore's abundance should have higher NPP than a two- or four-level food web in which herbivores have less predator control. Omnivory can also change the way energy is transferred in food webs by essentially "collapsing" trophic levels on one another. A four-level food web with a top consumer feeding on both the herbivore and the primary producer should have lower NPP than a four-level food web without omnivory. Even though the top consumer indirectly benefits the primary producer by feeding at the herbivore level, it partially negates this effect by directly feeding on the primary producer level as well.
3. One hypothesis, which focuses on the amount of NPP entering an ecosystem, suggests that bottom-up factors can influence the number of trophic levels in an ecosystem. Because tropical rainforests have higher NPP than deserts (see [Figure 57.4](#)), they may support more trophic levels if the amount of energy that can sustain populations at higher trophic levels is greater.

RECAP 57.4

1. The residence time of water depends on the rate at which it moves from one pool to another. Organisms, soil, and rivers all have short water residence times because they have relatively small volumes of water compared with lakes, glaciers, and oceans, and thus the rate of water movement from one pool to the next is much faster.
2. The concentration of CO₂ is rising in the atmosphere and oceans because of fossil-fuel burning. Today atmospheric CO₂ concentration is just over 400 parts per million, the highest recorded in the last 800,000 years. CO₂ is a greenhouse gas and, along with other greenhouse gases emitted by fossil-fuel burning, has caused a rise in Earth's temperature. The increase in CO₂ has resulted in a roughly 1 °C (1.8°F) rise in global temperatures compared with those from 1981 to 2010.

Slightly less than half of the CO₂ emitted by burning of fossil fuels has been absorbed by the oceans. CO₂ reacts with water to form carbonic acid (H₂CO₃). As levels of carbonic acid rise, the pH of seawater drops. This increase in acidity can have negative effects on many marine organisms that have calcium carbonate skeletons.

3. Nitrogen enters the biotic system as atmospheric N₂ and is fixed by bacteria into ammonia (NH₃). Ammonia is rapidly transformed into ammonium (NH₄⁺), which can then be used by plants and bacteria. Nitrifying bacteria can transform ammonium to nitrate (NO₃⁻), another form of nitrogen that plants and bacteria can use. Denitrifying bacteria take nitrate and convert it back to N₂ and N₂O gases, which are then released back into the atmosphere. Collectively, this microbial processing of nitrogen is very fast and accounts for about 95 percent of all natural nitrogen flux on Earth, making it a mostly biologically driven cycle.

Unlike nitrogen, phosphorus and sulfur are found in rocks and deep-sea sediments. They cycle very slowly through the geologic system because they require sedimentary rock formation, uplift, and weathering. Once they reach organisms, they rapidly cycle through the biological component of the ecosystem.

RECAP 57.5

1. Timber and fibers are provisioning services; coastal protection and erosion control are regulating services; water purification, habitat for fisheries, and carbon sequestration are supporting services; and tourism, recreation, and education are cultural services.
2. You could leave the mangrove ecosystem intact at the edge of the shoreline so that coastal protection would not be compromised. You could place shrimp farms inland behind these mangrove buffers, where the loss of forest would not have an appreciable effect on protection in extreme storms or tsunamis.

WORK WITH THE DATA, P. 1242

1.

2.

Under increased CO₂ and temperature, macroalgae and herbivores increase in biomass. When omnivores are present, this greater biomass will be utilized by omnivores, resulting in a stronger negative

interaction between them and their food sources. The stronger negative interaction will lead to a stronger indirect positive effect for benthic microalgae, which will not change in their biomass as a result. However, when omnivores are absent, macroalgae and herbivores will not be kept in check, and their negative interactions with benthic microalgae will grow even stronger, resulting in the decline of benthic microalgae.

3. The food webs and supporting data in the graphs show that with increased CO₂ and temperature, macroalgae and herbivores both increased in biomass, causing negative effects for benthic microalgae (the biomass declined). However, these negative effects for benthic microalgae did not manifest themselves when omnivores were present. By keeping macroalgae and herbivores in check under increased CO₂ and temperature, omnivores indirectly benefited benthic microalgae and allowed them to maintain the same biomass as that seen under ambient conditions.
4. If omnivores ceased feeding on macroalgae, benthic microalgae would decline in biomass because their competitors would increase. But the decline in biomass would be less than if these top consumers were removed altogether. The omnivores would still feed on the herbivores, creating a trophic cascade that would benefit benthic microalgae.

FIGURE QUESTIONS

Figure 57.1 Energy is said to flow through an ecosystem because it moves from the original source (either the sun or inorganic nutrients) to primary producers and consumers, and then is lost as metabolic heat. Nutrients are said to cycle because they continually move between living organisms and the abiotic components of an ecosystem.

Figure 57.8 The consumption and assimilation efficiencies are lower for herbivores because primary producers have structural and chemical defenses that make them harder to consume and digest than animals.

Figure 57.17 Industrial fixation of nitrogen accounts for 30 Tg of the 80 Tg total nitrogen fixed, or 37.5 percent.

APPLY WHAT YOU'VE LEARNED

1. Sea cucumbers feed on bacteria, benthic marine algae, and decaying organic matter such as feces. Thus they are omnivores, feeding from several levels in the food web. They are also decomposers because they feed on decaying organic matter. Their effect on NPP is hard to predict. By feeding on both primary producers and consumers, sea cucumbers may have little effect on NPP. Bacteria are also decomposers, so sea cucumbers may be feeding on a competitor.
2. According to the graph, TOC increases steadily over the 8-week period, but it increases significantly less in sea cucumber-grazed tanks. This indicates that grazing by sea cucumbers decreases TOC by a relatively constant amount over time. The decrease in TOC is evidence that organic carbon is being broken down, or recycled, into smaller inorganic compounds, which become available as nutrients for consumers in the ecosystem. In addition, some of the TOC is lost as CO₂ to the system through metabolism and respiration. Thus sea cucumbers have a noticeable effect on nutrient cycling in sediments.
3. There are at least two reasons why TOC continues to increase. First, a specific amount of mussel feces containing TOC is added each day (mirroring, albeit experimentally, what would happen in a mussel farm). Second, as this organic waste is added, bacteria increase as they feed on and decompose the waste. Both waste (dead organic matter) and bacterial biomass (live organic matter) are included in the TOC value. The experiment shows that TOC begins to level off as the experiment proceeds. For the control treatment (black circles) this likely means that, after an initial rise in bacterial population size, the bacteria begin to suffer food limitation. This is also shown in the sea cucumber treatment (clear circles), but with the added effect of sea cucumber grazing on TOC, which includes both waste and bacteria. As sea cucumbers feed, they break down and mineralize the TOC. However, the single cucumber used per tank in these trials is insufficient to cause a significant decline in TOC. It is likely that a larger sea cucumber population would further control TOC; if that population were large enough, it could solve the hypoxia problem.
4. As TOC levels increase, bacterial levels also increase, as bacteria use TOC as a food source and decompose it. Increased bacterial activity uses up oxygen, often resulting in hypoxia. In this experiment, oxygen levels would be decreasing as TOC increases; oxygen would decrease less as TOC begins to level off. The presence of sea cucumbers would make hypoxia less likely, because they would break down TOC and bacteria. Thus as TOC levels decline, oxygen levels will increase. But in this particular experiment, there is only one sea cucumber per test aquarium. This is not sufficient to break down most of the TOC; therefore oxygen levels are still likely to be too low for a healthy ecosystem.
5. The aquaculture manager chose to produce mussels in a natural coastal environment. This resulted in food for humans, but in the process he risked polluting the coastal environment. This is a trade-off between an economic good (food) and an environmental good (a clean, unpolluted coastal environment).

The addition of sea cucumbers would definitely be considered an ecosystem service. It uses a natural method (sea cucumbers, a species already present in the ecosystem) to solve a pollution problem, instead of resorting to chemical or physical removal of the TOC, which might cause further pollution and disruption of the environment.

Chapter 58

RECAP 58.1

1. Biodiversity loss is the loss of diversity at genetic, population, species, ecosystem, and global scales. The four major causes of biodiversity loss are habitat destruction (reduction in habitat quantity) and degradation (reduction in habitat quality); overharvesting of species; species invasions and emerging diseases; and climate change.
2. The heath hen's population sizes were reduced by hunting until only one very small population remained on the island of Martha's Vineyard, Massachusetts, in 1830. By 1908 only 50 birds remained. Although the population recovered to several thousand birds once a reserve was established for them, human-caused and natural factors led to a precipitous decline. The reduction in size caused inbreeding depression and demographic stochasticity and reduced the effective population size even more. By 1928 there were 2 females and 11 males, not enough individuals or genetic diversity to save the heath hen from extinction.
3. There are multiple reasons why it is hard to determine how many species are extinct or threatened with extinction. First, we do not know how many species live on Earth today because many have not been described. Some of those undescribed species may have already become extinct. Second, many described species are small, reclusive, and rare, and thus hard to keep track of. Third, it is difficult to determine whether a species is truly extinct, especially if it is rare. For example, there have been cases in which species were thought to be extinct but were later discovered to still be extant. Fourth, we rarely know all the interactions among species. It is hard to determine if the loss of one species will lead to the loss of others unless we have detailed ecological knowledge of all the species affected.

RECAP 58.2

1. The more fragmented a habitat is, the smaller and more isolated the fragments are and the greater the edge effects are. Fragmentation reduces the population sizes of species and isolates them from one another, reducing their ability to disperse among the greater metapopulation. Once population sizes are small and isolated, they become susceptible to extinction vortex processes (see [Figure 58.2](#)).
2. Gray wolves have been shown to create a trophic cascade that benefits hardwood trees such as aspens. Research by William Ripple and colleagues in Yellowstone National Park found that gray wolves, by feeding on elk, released aspen seedlings from herbivory, thus creating mature aspen forests. After wolves were hunted to extinction in Yellowstone in 1926, the number of aspens declined precipitously because of intensive elk grazing, as is shown in [Figure 56.9](#).
3. Three reasons why invasive species can have negative effects on biodiversity and ecosystems are (1) they can threaten native species with extinction through predation, competition, and disease transmission; (2) they can change the functions and services of ecosystems by affecting fire cycles, water availability, and sedimentation; and (3) they can change the genetic diversity of native species through hybridization events.
4. Yes, these data strongly suggest that climate warming is causing the butterfly species to shift its distribution to cooler, more optimal temperature conditions farther north. Likewise, emergence time is occurring earlier, when temperature conditions are optimal for that stage of the species' life history.

RECAP 58.3

1. Reserve design relies on three important principles: first, identify a large enough area that is relatively undisturbed and can serve as the core for protection; second, include a buffer zone around the core area that has some features required by the species of concern but is less restrictive to human use; and third, have habitat connectivity that keeps populations from becoming isolated from the greater metapopulation and thus subject to extinction. Taking into account global warming in terrestrial systems, the protected area should have similar protected areas, potentially connected by corridors of land, to the north (or south in the southern hemisphere) that could serve as a refuge from warming temperatures. An example is the Yellowstone to Yukon Conservation Initiative discussed in the chapter.
2. The California condor declined in its native range (British Columbia to Mexico) because of lead poisoning from carcasses containing lead shot, electrocution from power lines, the effects of pesticides on eggshell thinning, and hunting (ecological information). To save the California condor from extinction, the Endangered Species Act (institutional authority) was invoked and the species was removed from the wild in 1983 and subsequently bred in captivity. Although the breeding program was successful, ecological

information indicated that birds could not be released into the wild until the threats that caused their decline were mitigated. In 2008, the Ridley-Tree Condor Preservation Act was passed to require California hunters to use non-lead bullets when hunting in the condor's range. Along with passage of the act, public awareness was raised for hunters and cattle ranchers who mistakenly believed that condors killed livestock (socioeconomic interests).

WORK WITH THE DATA, [P. 1259](#)

1.	Distance interval (km)	Time interval (years)	Rate of spread (km/yr)
	0-140 = 140	1987-1993 = 6	140/6 = 23
	140-240 = 100	1993-1996 = 3	100/3 = 33
	240-325 = 85	1996-2002 = 6	85/6 = 14
	325-410 = 85	2002-2004 = 2	85/2 = 43
	410-445 = 35	2004-2006 = 2	35/2 = 18

The rates of spread do differ. They range from 14 to 43 km/year depending on the location.

- The average rate of *Bd* spread is 26 km/year. Assuming this average, the pathogen could spread 260 km east and south by 2016 (26 km/yr × 10 years).
- The majority of the habitat east and south of the last location where *Bd* was detected is mostly low elevation (0-199 meters), although there is a thin stretch of mountain habitat in the north. Given that far fewer frog species have become extinct because of *Bd* at elevations of 199 meters or less (30%), it seems less likely that the pathogen will be successful in this region of Panama. Based on the elevation data, the species extinction might reach 30%.

FIGURE QUESTIONS

Figure 58.2 The chytrid fungal pathogen leads to high mortality of frogs, thus lowering their population size. As population size declines, there is greater chance of inbreeding depression, genetic drift, and demographic stochasticity, which decrease genetic diversity. As genetic diversity declines, individual fitness declines, leading to lower reproduction and higher mortality in the population. This causes the population to continue to maintain a lower effective population size, which can ultimately lead to extinction at the population and species level.

Figure 58.3 Of the 59,033 species categorized by the IUCN, 1 percent are extinct and 20 percent are threatened. Birds have suffered the most extinctions (~150 species), but amphibians are most at risk of extinction (~1,900 species).

Figure 58.8 The highest fisheries exploitation is occurring off northern Europe in the northeast Atlantic Ocean and off Thailand and Vietnam in the South China Sea. Moderate exploitation is occurring in the northwest Atlantic Ocean off New England and Canada, as well as off the southern tip of Australia.

Figure 58.11 After the glaciers first started to retreat in North America about 18,000 years ago, the ranges of plant communities shifted northward and expanded considerably. Roughly 12,000 years ago, “no analog” plant communities, unlike any plant assemblage found today, formed under the unique climate conditions of the time. It may be that as climate changes, unique combinations of species will come together to form similar “no analog” communities.

APPLY WHAT YOU'VE LEARNED

- Vehicle collisions and hunting, both legal and illegal, are the two known major causes of puma deaths in these populations. Suspected and confirmed diseases together rank as the third most common cause. The two major causes result from human actions, particularly loss of habitat and/or habitat degradation, which forces pumas into urban and suburban areas. Disease is presumably a natural cause.
- As effective population size decreases, a population enters an “extinction vortex,” decreasing more every year and becoming more likely to go extinct. The pumas are living in an increasingly urban area and are at risk from vehicle collisions, hunting (both legal and illegal), and other urban-based factors, in addition to natural risks. As their population size declines, their genetic diversity also declines, making successful reproduction less likely. These factors suggest that, without some kind of intervention, pumas in these two populations will soon go extinct (with the Santa Ana population dying out first).
- Maintaining any population and saving it from loss or extinction contributes to biodiversity, because all species and populations are part of biodiversity. Each lost population represents the loss of a strand in the web of life, which is connected to other strands (species) in the community. The puma, as a top predator, contributes to control of its prey populations, which in turn affects lower levels in the food chain, down to producers. Loss of the puma could therefore affect community structure at several levels. This in turn will limit the effectiveness of ecosystem functions and the ecological services (both practical and aesthetic) provided by California ecosystems.
- Both populations are very small, so it makes sense to maximize the size of the gene pool by attempting to

conserve both populations. However, finding an appropriate protected area might skew the protection toward one population: the less urbanized Peninsular Range population. If a protected area is identified in the Peninsular Range, habitat corridors could be provided to connect this population with the Santa Ana population, thus extending protection to both populations.

5. In a coupled human-natural system, humans in urban and suburban areas are enlisted to increase biodiversity in their own habitats. For small species (such as pollinators), people can plant native gardens or even window boxes. This is more difficult, but still possible, for large top predators, such as pumas, with large geographic ranges. If conservationists establish a protected area for pumas in the Peninsular Range, a fairly large buffer zone would need to be established around it. The buffer zone would involve agricultural areas, and farmers would need to help maintain it. This would involve an extensive education program, since many farmers see pumas as “the enemy.” (In fact, the legal hunting that causes many puma deaths results from pumas feeding on livestock after being forced out of their natural habitat.) Farmers could be encouraged to establish edge habitats on their properties, allowing pumas safe passage to wilder areas. Coupled human-natural systems friendly to pumas would be more difficult to establish in urban areas, but wildlife corridors—particularly those allowing safe passage across highways—would be one obvious example.

GLOSSARY

3' end

(3 prime) The end of a DNA or RNA strand that has a free hydroxyl group at the 3' carbon of the sugar (deoxyribose or ribose).

5' cap

(5 prime) Methylated guanine nucleotide bonded to the 5' end of eukaryotic mRNA.

5' end

The end of a DNA or RNA strand that has a free phosphate group at the 5' carbon of the sugar (deoxyribose or ribose).

A

A horizon

See topsoil.

abiotic

(a' bye ah tick) [Gk. *a*: not + *bios*: life] Nonliving components of the environment including its physical and chemical characteristics. (Contrast with biotic.)

abomasum

(a bo mey' sum) The fourth of the four chambers of the stomach in ruminants; the true stomach.

abortion

Any termination of pregnancy, whether induced or natural (in which case it is called a spontaneous abortion), that occurs after a fertilized egg is successfully implanted in the uterus.

abscisic acid (ABA)

(ab sighs' ik) A plant growth substance with growth-inhibiting action. Causes stomata to close; involved in a plant's response to salt and drought stress.

abscission

(ab sizh' un) [L. *abscissio*: break off] The process by which leaves, petals, and fruits separate from a plant.

aboral

The opposite side of the body from the mouth.

absorption spectrum

A graph of light absorption versus wavelength of light; shows how much light is

absorbed at each wavelength.

absorptive heterotrophs

Organisms (primarily fungi) that feed by **absorptive heterotrophy**, i.e., by secreting digestive enzymes into the environment to break down large food molecules, then absorbing the breakdown products.

absorptive state

State in which food is in the gut and nutrients are being absorbed. (Contrast with postabsorptive state.)

acquired immune deficiency syndrome (AIDS)

Decline in immune system function due to depletion of T_H cells and macrophages infected with HIV.

accessory fruits

A fruit in which some of the flesh develops from tissue exterior to the carpel.

accessory sex organs

Anatomical structures that allow transfer of sperm from male to female for internal fertilization. (Contrast with primary sex organs.)

acclimation

Refers to increased tolerance for environmental extremes (e.g., extreme cold) after prior exposure to them.

acclimatization

Refers to intrinsic seasonal adjustments in the “set points” of an animal’s physiological functioning (e.g., metabolic rate).

acetyl coenzyme A (acetyl CoA)

A compound that reacts with oxaloacetate to produce citrate at the beginning of the citric acid cycle; a key metabolic intermediate in the formation of many compounds.

acetylcholine (ACh)

A neurotransmitter that carries information across vertebrate neuromuscular junctions and some other synapses. It is then broken down by the enzyme acetylcholinesterase (AChE).

acid

[L. *acidus*: sharp, sour] A substance that can release a proton in solution. (Contrast with base.)

acid growth hypothesis

The hypothesis that auxin increases proton pumping, thereby lowering the pH of the cell wall and activating enzymes that loosen polysaccharides. Proposed to explain auxin-induced cell expansion in plants.

acid rain

Rain that has a lower pH than normal as a result of acid-forming precursor molecules introduced into the atmosphere by human activities.

acoelomate

An animal that does not have a coelom.

acrosome

(a' krow soam) [Gk. *akros*: highest + *soma*: body] The structure at the forward tip of an animal sperm, which is the first to fuse with the egg membrane and enter the egg cell.

ACTH

See corticotropin.

actin

[Gk. *aktis*: ray] A protein that makes up the cytoskeletal microfilaments in eukaryotic cells and is one of the two contractile proteins in muscle. (See *also* myosin.)

action potentials (APs)

Generated by neurons, these are electrical signals that transmit information via waves of depolarization or hyperpolarization of the cell membrane.

action spectrum

A graph of a biological process versus light wavelength; shows which wavelengths are involved in the process.

activation energy (E_a)

The energy barrier that blocks the tendency for a chemical reaction to occur.

activation gate

The property of a voltage-gated Na^+ ion channel that increases its permeability to Na^+ ions when the membrane is depolarized.

activator

A transcription factor that stimulates transcription when it binds to a gene's promoter. (Contrast with repressor.)

active site

The region on the surface of an enzyme or ribozyme where the substrate binds, and where catalysis occurs.

active transport

The energy-dependent transport of a substance across a biological membrane against a concentration gradient—that is, from a region of low concentration (of that substance) to one of high concentration. (See *also* primary active transport, secondary active transport. Contrast with facilitated diffusion, passive transport.)

adaptation

(a dap tay' shun) (1) In evolutionary biology, a particular structure, physiological process, or behavior that makes an organism better able to survive and reproduce. Also, the evolutionary process that leads to the development or persistence of such a trait. (2) In sensory neurophysiology, a sensory cell's loss of sensitivity as a result of repeated stimulation.

adaptive defenses

One of the two general types of defenses against pathogens. Involves antibody proteins and other proteins that recognize, bind to, and aid in the destruction of specific viruses and bacteria. Present only in vertebrate animals. (Contrast with innate defenses.)

adaptive radiation

A series of evolutionary events that results in an array (radiation) of related species that live in a variety of environments, differing in the characteristics each uses to exploit those environments.

addition rule

The probability of one of two or more events that are mutually exclusive is the sum of their independent probabilities.

adenine (A)

(a' den een) A nitrogen-containing base found in nucleic acids, ATP, NAD, and other compounds.

adeno-associated virus

A small, non-pathogenic virus with a single-strand DNA genome, that can be used for gene therapy in humans and does not integrate unto the host chromosomes.

ADH

See vasopressin.

adhesion

Binding of one cell or substance to another.

adrenal cortex

The outer region of the adrenal gland that produces and secretes steroid hormones.

adrenal gland

(a dree' nal) [L. *ad*: toward + *renes*: kidneys] An endocrine gland located near the kidneys of vertebrates, consisting of two parts, the adrenal cortex and adrenal medulla.

adrenal medulla

Tissue that makes up the core of the adrenal gland and secretes epinephrine and norepinephrine.

adrenergic receptors

G protein-coupled receptor proteins that bind to the hormones epinephrine and norepinephrine, triggering specific responses in the target cells.

adrenocorticotrophic hormone (ACTH)

See corticotropin.

adventitious roots

(ad ven ti' shus) [L. *adventitius*: arriving from outside] Roots originating from the stem at ground level or below; typical of the fibrous root system of monocots.

aerenchyma

In plants, parenchymal tissue containing air spaces.

aerobic

(air oh' bic) [Gk. *aer*: air + *bios*: life] In the presence of oxygen; requiring or using oxygen (as in **aerobic metabolism**). (Contrast with anaerobic.)

aerotolerant anaerobe

A prokaryote that does not require an oxygen atmosphere for survival, but which can live while exposed to O₂.

afferent

(af' ur unt) [L. *ad*: toward + *ferre*: to carry] Carrying to, as in neurons that carry impulses to the central nervous system (**afferent neurons**), or a blood vessel that carries blood to a structure (**afferent arterioles**). (Contrast with efferent.)

after-hyperpolarization

A fall in membrane potential below normal resting level following an action potential.

aggregate fruit

A fruit that develops from several carpels from the same flower.

agonist

A chemical substance (e.g., a neurotransmitter) that elicits a specific response in a cell or tissue. (Contrast with antagonist.)

AIDS

See acquired immune deficiency syndrome.

air sacs

Structures in the respiratory system of birds that receive inhaled air; they keep fresh air flowing unidirectionally through the lungs, but are not themselves gas exchange surfaces.

albedo effect

(al bee' doh) [L. *albus*: white] The solar radiation reflected by the surface of Earth.

alcoholic fermentation

See fermentation.

aldosterone

(al dohs' ter own) A steroid hormone produced in the adrenal cortex of mammals. Promotes secretion of potassium and reabsorption of sodium in the kidney.

aleurone layer

(al yu' rown) In some seeds, a tissue that lies beneath the seed coat and surrounds the endosperm. Secretes digestive enzymes that break down macromolecules stored in the endosperm.

allantoic membrane

In animal development, an outgrowth of extraembryonic endoderm plus adjacent mesoderm that forms the allantois, a saclike structure that stores metabolic wastes produced by the embryo.

allantois

(al' lun toh is) [Gk. *allant*: sausage] An extraembryonic membrane enclosing a sausage-shaped sac that stores the embryo's nitrogenous wastes.

Allee effect

An increase in the population growth rate (r) as the population density decreases.

allele

(a leel') [Gk. *allos*: other] The alternate form of a genetic character found at a given locus on a chromosome.

allergic reaction

[Ger. *allergie*: altered] An overreaction of the immune system to amounts of an antigen that do not affect most people; often involves IgE antibodies.

allopatric speciation

(al' lo pat' rick) [Gk. *allos*: other + *patria*: homeland] The formation of two species from one when reproductive isolation occurs because of the interposition of (or crossing of) a physical geographic barrier such as a river. Also called geographic speciation. (Contrast with sympatric speciation.)

allopolyploidy

The possession of more than two chromosome sets that are derived from more than one species.

allosteric regulation

(al lo steer' ik) [Gk. *allos*: other + *stereos*: structure] Regulation of the activity of a protein (usually an enzyme) by the binding of an effector molecule to a site other than the active site.

alpha diversity

Species diversity at the local or community scale. (Compare with beta diversity, gamma diversity.)

α (alpha) helix

A prevalent type of secondary protein structure; a right-handed spiral.

alternation of generations

The succession of multicellular haploid and diploid phases in some sexually reproducing organisms, notably plants.

alternative hypothesis

In statistical inference, the hypothesis that contrasts with the null hypothesis; typically the hypothesis of primary interest.

alternative splicing

A process for generating different mature mRNAs from a single gene by splicing together different sets of exons during RNA processing.

alternative states

Different community assemblages that develop at the same location under similar environmental conditions.

altricial

Born or hatched in a relatively undeveloped state that requires care and feeding by the parents.

altruistic

Pertaining to behavior that benefits other individuals at a cost to the individual who performs it.

alveolus

(al ve' o lus) (plural: alveoli) [L. *alveus*: cavity] A small, baglike cavity, especially the blind sacs of the lung.

amacrine cells

Cells in the retina that communicate laterally between ganglion and bipolar cells.

amensalism

A type of interaction in which one species is harmed and the other is unaffected. (Contrast with competition, commensalism, mutualism.)

amine hormones

Small hormone molecules synthesized from single amino acids (e.g., thyroxine and epinephrine).

amino acid

An organic compound containing both NH_2 and COOH groups. Proteins are polymers of amino acids.

ammonia

NH_3 , the most common nitrogenous waste. (Compare with urea, uric acid.)

ammonotelic

(am moan' o teel' ic) [Gk. *telos*: end] Pertaining to an organism in which the final product of breakdown of nitrogen-containing compounds (primarily proteins) is ammonia. (Contrast with ureotelic, uricotelic.)

amnion

(am' nee on) The fluid-filled sac within which the embryos of reptiles (including birds) and mammals develop.

amniote egg

A shelled egg surrounding four extraembryonic membranes and embryo-nourishing yolk. This evolutionary adaptation permitted mammals and reptiles to live and reproduce in drier environments than can most amphibians.

amniotic fluid

The fluid in the amniotic sac that contains mammalian and reptilian embryos.

amphipathic

(am' fi path' ic) [Gk. *amphi*: both + *pathos*: emotion] Of a molecule, having both hydrophilic and hydrophobic regions.

amplitude

The magnitude of change over the course of a regular cycle.

amygdala

A component of the limbic system that is involved in fear and the memory of fearful experiences.

anabolic reaction

(an uh bah' lik) [Gk. *ana*: upward + *ballein*: to throw] A synthetic reaction in which simple molecules are linked to form more complex ones; requires an input of energy and captures it in the chemical bonds that are formed. (Contrast with catabolic reaction.)

anaerobic

(an ur row' bic) [Gk. *an*: not + *aer*: air + *bios*: life] Occurring without the use of molecular oxygen, O₂. (Contrast with aerobic.)

anaerobic respiration

A metabolic pathway in which glucose is catabolized in the absence of oxygen.

analogous

In biology, refers to similar structures found in two or more groups of organisms, but with separate, independent evolutionary origins. An example is the wings of bats and the wings of birds, which evolved independently as wings from wingless ancestors.

ancestral trait

The trait originally present in the ancestor of a given group; may be retained or

changed in the descendants of that ancestor.

androgen

(an' dro jen) Any of the several male sex steroids (most notably testosterone).

aneuploidy

(an' you ploy dee) A condition in which one or more chromosomes or pieces of chromosomes are either lacking or present in excess.

angiosperms

Flowering plants; one of the two major groups of living seed plants. (See *also* gymnosperms.)

angiotensin

(an' jee oh ten' sin) A peptide hormone that raises blood pressure by causing peripheral vessels to constrict. Also maintains glomerular filtration by constricting efferent vessels and stimulates thirst and the release of aldosterone.

angular gyrus

A part of the human brain believed to be essential for integrating spoken and written language.

animal hemisphere

The metabolically active upper portion of some animal eggs, zygotes, and embryos; does not contain the dense nutrient yolk. (Contrast with vegetal hemisphere.)

animal physiology

The study of animal form and function.

animal pole

The point at the end of the developing egg where yolk is least concentrated.

anion

(an' eye on) [Gk. *ana*: upward] A negatively charged ion. (Contrast with cation.)

annual

A plant whose life cycle is completed in one growing season. (Contrast with biennial, perennial.)

antagonist

A biochemical substance (e.g., a drug) that blocks the normal action of another biochemical substance. (Contrast with agonist.)

anterior pituitary

The portion of the vertebrate pituitary gland that derives from gut epithelium. Produces trophic hormones.

anterior

Toward or pertaining to the tip or headward region of the body axis. (Contrast with

posterior.)

anther

(an' thur) [Gk. *anthos*: flower] A pollen-bearing portion of the stamen of a flower.

antheridium

(an' thur id' ee um) [Gk. *antheros*: blooming] The multicellular structure that produces the sperm in nonvascular land plants and ferns.

antibody

One of the myriad proteins produced by the immune system that specifically binds to a foreign substance in blood or other tissue fluids and initiates its removal from the body.

anticodon

The three nucleotides in transfer RNA that pair with a complementary triplet (a codon) in messenger RNA.

antidiuretic hormone (ADH)

See vasopressin.

antigen

(an' ti jun) Any substance that stimulates the production of an antibody or antibodies in the body of a vertebrate.

antigen presentation

In cellular immunity, a process in which a cell ingests and digests an antigen, and then exposes fragments of that antigen to the outside of the cell, bound to proteins in the cell's cell membrane.

antigenic determinant

The specific region of an antigen that is recognized and bound by a specific antibody. Also called an epitope.

antiparallel

Pertaining to molecular orientation in which a molecule or parts of a molecule have opposing directions.

antiporter

A membrane transport protein that moves one substance in one direction and another in the opposite direction. (Contrast with symporter, uniporter.)

antisense RNA

A single-stranded RNA molecule complementary to, and thus targeted against, an mRNA of interest to block its translation.

anus

(a' nus) An opening through which solid digestive wastes are expelled, located at the posterior end of a tubular gut.

aorta

(a or' tah) [Gk. *aorte*: aorta] The main trunk of the arteries leading to the systemic (as opposed to the pulmonary) circulation.

aortic body

A chemosensor in the aorta that senses a decrease in blood supply or a dramatic decrease in partial pressure of oxygen in the blood.

aortic valve

A one-way valve between the left ventricle of the heart and the aorta that prevents backflow of blood into the ventricle when it relaxes.

aphasia

A deficit in the ability to use or understand words.

apical dominance

In plants, inhibition by the apical bud of the growth of axillary buds.

apical hook

A form taken by the stems of many eudicot seedlings that protects the delicate shoot apex while the stem grows through the soil.

apical meristem

The meristem at the tip of a shoot or root; responsible for a plant's primary growth.

apomixis

(ap oh mix' is) [Gk. *apo*: away from + *mixis*: sexual intercourse] The asexual production of seeds.

apoplast

(ap' oh plast) In plants, the continuous meshwork of cell walls and extracellular spaces through which material can pass without crossing a plasma membrane. (Contrast with symplast.)

apoptosis

(ap uh toh' sis) A series of genetically programmed events leading to cell death.

appendix

A small blind-end sac that is attached to the initial segment of the colon.

aquaporin

A transport protein in plant and animal cell membranes through which water passes in osmosis.

aquifer

A large pool of groundwater.

archegonium

(ar' ke go' nee um) The multicellular structure that produces eggs in nonvascular land plants, ferns, and gymnosperms.

archenteron

(ark en' ter on) [Gk. *archos*: first + *enteron*: bowel] The earliest primordial animal digestive tract.

arcuate nucleus

A group of neurons in the hypothalamus that produce and secrete many neuroendocrines and are involved in regulation of appetite.

arteriole

A small blood vessel arising from an artery that feeds blood into a capillary bed.

artery

A muscular blood vessel carrying oxygenated blood away from the heart to other parts of the body. (Contrast with vein.)

artificial insemination

An infertility treatment that involves the artificial introduction of sperm into the woman's reproductive tract.

ascospores

Haploid spores contained with the sexual reproductive structure (the ascus) of sac fungi.

ascus

(ass' cus) (plural: asci) [Gk. *askos*: bladder] In sac fungi, the club-shaped sporangium within which spores (ascospores) are produced by meiosis.

assimilation efficiency

The proportion of ingested biomass that consumers assimilate by digestion.

assisted reproductive technologies (ARTs)

Any of several procedures that remove unfertilized eggs from the ovary, combine them with sperm outside the body, and then place fertilized eggs or egg–sperm mixtures in the appropriate location in a female's reproductive tract for development.

association cortex

In the vertebrate brain, the portion of the cortex involved in higher-order information processing, so named because it integrates, or associates, information from different sensory modalities and from memory.

asthenosphere

(ass thenn' o sphere) [Gk. *asthenes*: weak] The viscous, malleable (changeable) layer of Earth's mantle. It is overlain by the solid lithospheric plates.

astrocyte

[Gk. *astron*: star] A type of glial cell that contributes to the blood–brain barrier by surrounding the smallest, most permeable blood vessels in the brain.

atherosclerosis

(ath' er oh sklair oh' sis) [Gk. *athero*: gruel, porridge + *skleros*: hard] A disease of the lining of the arteries characterized by fatty, cholesterol-rich deposits in the walls of the arteries. When fibroblasts infiltrate these deposits and calcium precipitates in them, the disease becomes **arteriosclerosis**, or "hardening of the arteries."

atmosphere

A thin layer of gases surrounding Earth composed of nitrogen gas, oxygen, argon, carbon dioxide, and traces of hydrogen, helium, ozone, methane, and many other gases.

atom

[Gk. *atomos*: indivisible] The smallest unit of a chemical element. Consists of a nucleus and one or more electrons.

atomic number

The number of protons in the nucleus of an atom; also equals the number of electrons around the neutral atom. Determines the chemical properties of the atom.

atomic weight

The average of the mass numbers of a representative sample of atoms of an element, with all the isotopes in their normally occurring proportions. Also called atomic mass.

ATP (adenosine triphosphate)

An energy-storage compound containing adenine, ribose, and three phosphate groups. When it is formed from ADP, useful energy is stored; when it is broken down (to ADP or AMP), energy is released to drive endergonic reactions.

ATP synthase

An integral membrane protein that couples the transport of protons with the formation of ATP.

atrial natriuretic peptide (ANP)

A hormone released by the atrial muscle fibers of the heart when they are overly stretched, which decreases reabsorption of sodium by the kidney and thus blood volume.

atrioventricular node

A modified node of cardiac muscle that organizes the action potentials that control contraction of the ventricles.

atrioventricular (AV) valve

A heart valve between an atrium and a ventricle.

atrium

(a' tree um) [L. *atrium*: central hall] An internal chamber. In the hearts of vertebrates, the thin-walled chamber(s) entered by blood on its way to the ventricle(s). Also, the outer ear.

autocatalysis

[Gk. *autos*: self + *kata*: to break down] A positive feedback process in which an activated enzyme acts on other inactive molecules of the same enzyme to activate them.

autocrine

A chemical signal that binds to and affects the cell that makes it. (Contrast with paracrine.)

autoimmunity

An immune response by an organism to its own molecules or cells.

autonomic nervous system (ANS)

The portion of the peripheral nervous system that controls such involuntary functions as those of guts and glands. Also called the involuntary nervous system.

autonomous specification

Determination of cell fates due to informational molecules originally present in the egg.

autophagy

The programmed destruction of a cell's components.

autopolyploidy

The possession of more than two entire chromosome sets that are derived from a single species.

autoregulatory mechanisms

In mammalian circulatory systems, local control of blood flow through capillary beds by constriction or dilation of incoming arterioles in response to local metabolite concentrations.

autosome

Any chromosome (in a eukaryote) other than a sex chromosome.

autotroph

(au' tow trowf) [Gk. *autos*: self + *trophe*: food] An organism that is capable of living exclusively on inorganic materials, water, and some energy source such as sunlight (photoautotrophs) or chemically reduced matter (see chemoautotrophs). (Contrast with heterotroph.)

auxin

(awk' sin) [Gk. *auxein*: to grow] In plants, a substance (the most common being indoleacetic acid) that regulates growth and various aspects of development.

avirulence (Avr) genes

Genes in a pathogen that may trigger defenses in plants. (See gene-for-gene concept.)

Avogadro's number

The number of atoms or molecules in a mole (weighed out in grams) of a substance, calculated to be 6.023×10^{23} .

axillary bud

A bud that forms in the angle (axil) where a leaf meets a stem.

axon

[Gk. axle] The process (branching structure) of a neuron that conducts action potentials away from the cell body. (See *also* dendrites.)

axon hillock

The junction between an axon and the neuron's cell body; where action potentials are generated.

axon terminal

The end portion of an axon, which passes action potentials to another cell. Axon terminals can form synapses and release neurotransmitter.

B**B cell**

A type of lymphocyte involved in the humoral immune response of vertebrates. Upon recognizing an antigenic determinant, a B cell develops into a plasma cell, which secretes an antibody. (Contrast with T cell.)

B horizon

See subsoil.

bacillus

(bah sil' us) [L: little rod] Any of various rod-shaped bacteria.

bacterial conjugation

See conjugation.

bacteriophage

(bak teer' ee o fayj) [Gk. *bakterion*: little rod + *phagein*: to eat] Any of a group of viruses that infect bacteria. Also called phage.

bacteroids

Nitrogen-fixing organelles that develop from endosymbiotic bacteria.

bar chart

A figure that displays frequency distributions of categorical data using bar lengths to represent relative frequency.

bark

All tissues external to the vascular cambium of a plant.

baroreceptor

[Gk. *baros*: weight] A pressure-sensing cell or organ. Sometimes called a stress receptor.

basal metabolic rate (BMR)

The minimum rate of energy turnover in an awake (but resting) bird or mammal that is not expending energy for thermoregulation.

base

(1) A substance that can accept a hydrogen ion in solution. (Contrast with acid.) (2) In nucleic acids, the purine or pyrimidine that is attached to each sugar in the sugar–phosphate backbone.

base pair (bp)

In double-stranded DNA, a pair of nucleotides formed by the complementary base pairing of a purine on one strand and a pyrimidine on the other. (See complementary base pairing.)

basidioma

(plural: basidiomata) A fruiting structure produced by club fungi.

basidium

(bass id' ee yum) In club fungi, the characteristic sporangium in which four **basidiospores** are formed by meiosis and then borne externally before being shed.

Batesian mimicry

The convergence in appearance of an edible species (mimic) with an unpalatable species (model).

behavioral ecology

An evolutionary approach to the study of animal behavior that studies how behaviors are adaptive in different environmental conditions.

behaviorism

One of two classical approaches to the study of proximate causes of animal behavior, derived from the discoveries of Ivan Pavlov and focused on laboratory studies. (Compare with ethology.)

benign

A tumor that grows to a limited extent and does not spread to other parts of the body. (Contrast with malignant.)

beta diversity

The change in species number and composition, or turnover of species, across a landscape. (Compare with alpha diversity, gamma diversity.)

β (beta) pleated sheet

A type of protein secondary structure; results from hydrogen bonding between polypeptide regions running antiparallel to each other.

biased gene conversion

A mechanism of concerted evolution in which a DNA repair system appears biased in favor of using particular nucleotide sequences as templates for repair, resulting in the rapid spread of the favored sequence across all copies of the gene. (See concerted evolution.)

bicuspid valve

The left AV valve. So named because it has two leaves.

biennial

A plant whose life cycle includes vegetative growth in the first year and flowering and senescence in the second year. (Contrast with annual, perennial.)

bilateral symmetry

The condition in which only the right and left sides of an organism, divided by a single plane through the midline, are mirror images of each other.

bilayer

A structure that is two layers in thickness. In biology, most often refers to the phospholipid bilayer of membranes. (See phospholipid bilayer.)

bile

A secretion of the liver made up of bile salts synthesized from cholesterol, various phospholipids, and bilirubin (the breakdown product of hemoglobin). Emulsifies fats in the small intestine.

binary fission

Reproduction of a prokaryote by division of a cell into two comparable progeny cells.

bindin

Species specific recognition molecule on the sperm acrosomal process.

binocular vision

Overlapping visual fields of an animal's two eyes; allows the animal to see in three dimensions.

binomial nomenclature

[Gk. two names] A taxonomic naming system in which each species is given a binomial, a genus name followed by a species name.

biodiversity

The diversity of important ecological entities that span multiple spatial scales, from genes to populations to species to communities.

biofilm

A community of microorganisms embedded in a polysaccharide matrix, forming a highly resistant coating on almost any moist surface.

biogeochemical cycle

Movement of inorganic elements such as water, nitrogen, phosphorus, and carbon through living organisms and the physical environment.

biogeographic region

Distinct regions of biota characterized by different species that occur at the continental-scale. (Contrast with biome.)

biogeography

The scientific study of the distribution and diversity of organisms across Earth.

bioinformatics

The use of computers and/or mathematics to analyze complex biological information, such as DNA sequences.

biological control

The use of natural enemies (predators, parasites, or pathogens) to reduce the population density of an economically damaging (pest) species.

biological species concept

The definition of a species as a group of actually or potentially interbreeding natural populations that are reproductively isolated from other such groups. (Contrast with lineage species concept; morphological species concept.)

biology

[Gk. *bios*: life + *logos*: study] The scientific study of living things.

biome

(bye' ome) A major division of the ecological communities of Earth, characterized primarily by distinctive vegetation and the annual patterns of temperature and precipitation. A given biogeographic region contains many different biomes.

biosphere

(bye' oh sphere) All regions of Earth (terrestrial and aquatic) and Earth's atmosphere in which organisms can live.

biota

(bye oh' tah) All of the organisms— animals, plants, fungi, and microorganisms— found in a given area. (Contrast with flora, fauna.)

biotechnology

The use of living cells or organisms to produce materials useful to humans.

biotic

(bye ah' tick) [Gk. *bios*: life] Living components of the environment such as organisms. (Contrast with abiotic.)

biotic resistance

The ability of resident species to exclude or slow the population growth of non-

native species.

bipedal locomotion

Terrestrial locomotion by means of two rear limbs or legs.

bipolar cells

Cells in the retina that communicate between photoreceptors and ganglion cells.

blastocoel

(blass' toe seal) [Gk. *blastos*: sprout + *koilos*: hollow] The central, hollow cavity of a blastula.

blastocyst

(blass' toe cist) An early embryo formed by the first divisions of the fertilized egg (zygote). In mammals, a hollow ball of cells.

blastoderm

A layer of undifferentiated cells that are a very early stage of development prior to the specification of the embryonic axis.

blastodisc

(blass' toe disk) An embryo that forms as a disc of cells on the surface of a large yolk mass; comparable to a blastula, but occurring in animals such as birds and reptiles, in which the massive yolk restricts complete cleavage.

blastomere

Any of the cells produced by the early divisions of a fertilized animal egg.

blastopore

The opening created by the invagination of the vegetal pole during gastrulation of animal embryos.

blastula

(blass' chu luh) An early stage of the animal embryo; in many species, a hollow sphere of cells surrounding a central cavity, the blastocoel. (Contrast with blastodisc.)

block to polyspermy

Any of several responses to entry of a sperm into an egg that prevent more than one sperm from entering the egg.

blood clotting

A cascade of events involving platelets and circulating proteins (clotting factors) that seals damaged blood vessels.

blood plasma

(plaz' muh) The liquid portion of blood, in which blood cells and other particulates are suspended.

blood–brain barrier

The selective impermeability of blood vessels in the brain that prevents most chemicals from diffusing from the blood into the brain.

blue-light receptors

Pigments in plants that absorb blue light (400–500 nm). These pigments mediate many plant responses including photo-tropism, stomatal movements, and expression of some genes.

BMR

See basal metabolic rate.

body cavity

An internal, fluid-filled space, enclosed by mesoderm in triploblastic animals.

body plan

The general structure of an animal, the arrangement of its organ systems, and the integrated functioning of its parts.

Bohr effect

A shift in the O₂-binding curve of hemoglobin in response to excess H⁺ ions such that the hemoglobin releases more O₂ in tissues where pH is low.

bone

A rigid component of vertebrate skeletal systems that contains an extracellular matrix of insoluble calcium phosphate crystals as well as collagen fibers.

Bowman's capsule

An elaboration of the renal tubule, composed of podocytes, that surrounds and collects the filtrate from the glomerulus.

brain

The centralized integrative center of a nervous system.

brainstem

The portion of the vertebrate brain between the spinal cord and the forebrain, made up of the medulla, pons, and midbrain.

brassinosteroids

Plant steroid hormones that mediate light effects promoting the elongation of stems and pollen tubes.

Broca's area

A portion of the human brain essential for speech. Located in the frontal lobe just in front of the primary motor cortex.

bronchioles

The smallest airways in a vertebrate lung, branching off the bronchi.

bronchus

(plural: bronchi) The major airway(s) branching off the trachea into the vertebrate lung.

brown fat

In mammals, fat tissue that is specialized to produce heat. It has many mitochondria and capillaries, and a protein that uncouples oxidative phosphorylation.

bud

A protuberance on a stem that contains an undeveloped leaf, shoot, or flower.

budding

Asexual reproduction in which a more or less complete new organism grows from the body of the parent organism, eventually detaching itself.

buffer

A substance that can transiently accept or release hydrogen ions and thereby resist changes in pH.

bulbourethral glands

Secretory structures of the human male reproductive system that produce a small volume of an alkaline, mucoid secretion that helps neutralize acidity in the urethra and lubricate it to facilitate the passage of semen.

bulbus arteriosus

The last chamber of the fish heart.

bulk flow

The movement of a solution from a region of higher pressure potential to a region of lower pressure potential.

bulk transport

See solvent drag.

bundle of His

Fibers of modified cardiac muscle that conduct action potentials from the atria to the ventricular muscle mass.

bundle sheath cell

Part of a tissue that surrounds the veins of plants.

C**C horizon**

See parent rock.

C₃ plants

Plants that produce 3PG as the first stable product of carbon fixation in photosynthesis and use ribulose biphosphate as a CO₂ receptor.

C₄ plants

Plants that produce oxaloacetate as the first stable product of carbon fixation in photosynthesis and use phosphoenolpyruvate as a CO₂ acceptor. C₄ plants also perform the reactions of C₃ photosynthesis.

calcitonin

Hormone produced by the thyroid gland; lowers blood calcium and promotes bone formation. (Contrast with parathyroid hormone.)

calcitriol

A hormone derived from vitamin D whose actions include stimulating the cells of the digestive tract to absorb calcium from ingested food.

calorie

[L. *calor*: heat] The amount of heat required to raise the temperature of 1 gram of water by 1°C. Physiologists commonly use the kilocalorie (kcal) as a unit of measure (1 kcal = 1,000 calories). Nutritionists also use the **kilocalorie**, but refer to it as the **Calorie** (**Cal**, capital C).

Calvin cycle

The stage of photosynthesis in which CO₂ reacts with RuBP to form 3PG, 3PG is reduced to a sugar, and RuBP is regenerated, while other products are released to the rest of the plant. Also known as the Calvin–Benson cycle.

CAM

See crassulacean acid metabolism.

Cambrian explosion

The rapid diversification of multicellular life that took place during the Cambrian period.

cAMP (cyclic AMP)

A compound formed from ATP that acts as a second messenger.

cancellous bone

A type of bone with numerous internal cavities that make it appear spongy, although it is rigid. (Contrast with compact bone.)

capillaries

[L. *capillaris*: hair] Very small tubes, especially the smallest blood-carrying vessels of animals between the termination of the arteries and the beginnings of the veins. **Capillary beds** are networks of capillaries where materials are exchanged between the blood and the interstitial fluid.

capsid

The outer shell of a virus that encloses its nucleic acid.

capsule

In some prokaryotes, a dense layer of polymers that surrounds the cell wall.

carbohydrases

Digestive enzymes that hydrolyze carbohydrates.

carbohydrates

Organic compounds containing carbon, hydrogen, and oxygen in the ratio 1:2:1 (i.e., with the general formula $C_nH_{2n}O_n$). Common examples are sugars, starch, and cellulose.

carbon skeleton

The chains or rings of carbon atoms that form the structural basis of organic molecules. Other atoms or functional groups are attached to the carbon atoms.

carbonic anhydrase (CA)

An enzyme that catalyzes the hydration of CO_2 to produce carbonic acid.

carboxylase

An enzyme that catalyzes the addition of carboxyl functional groups ($O=C—OH$) to a substrate.

cardiac cycle

Contraction of the two atria of the heart, followed by contraction of the two ventricles and then relaxation.

cardiac muscle

A type of muscle tissue that makes up, and is responsible for the beating of, the heart. Characterized by branching cells with single nuclei and a striated (striped) appearance. (Contrast with smooth muscle, skeletal muscle.)

cardiovascular system

[Gk. *kardia*: heart + L. *vasculum*: small vessel] The heart, blood, and vessels are of a circulatory system.

carnivore

[L. *carn*: flesh + *vorare*: to devour] An organism that eats animal tissues. (Contrast with detritivore, herbivore, omnivore.)

carnivorous plant

Plant capable of trapping and digesting animals to obtain nutrients.

carnivory

An act of predation in which the predator and prey are both animals. (Contrast with herbivory, parasitism, or omnivory).

carotid body

A chemosensor in the carotid artery that senses a decrease in blood supply or a dramatic decrease in partial pressure of oxygen in the blood.

carpel

(kar' pel) [Gk. *karpos*: fruit] The organ of the flower that contains one or more ovules.

carrier proteins

Proteins that bind another substance to transport it from one location to another; carriers bind small molecules and transport them across membranes.

carrying capacity (*K*)

The maximum number of individuals in a population (i.e., maximum population size) that can be supported by the resources present in a given environment.

cartilage bone

A type of bone that begins its development as a cartilaginous structure resembling the future mature bone, then gradually hardens into mature bone. (Contrast with membranous bone.)

cartilage

In vertebrates, a tough connective tissue found in joints, the outer ear, and elsewhere. Forms the entire skeleton in some animal groups.

Casparian strip

A band of cell wall containing suberin and lignin, found in the endodermis. Restricts the movement of water across the endodermis.

caspase

One of a group of proteases that catalyze cleavage of target proteins and are active in apoptosis.

catabolic reaction

(kat uh bah' lik) [Gk. *kata*: to break down + *ballein*: to throw] A synthetic reaction in which complex molecules are broken down into simpler ones and energy is released. (Contrast with anabolic reaction.)

catabolite repression

In the presence of abundant glucose, the diminished synthesis of catabolic enzymes for other energy sources.

categorical variables

Variables that take on qualitative categories as values, such as human blood types (A, AB, B, or O).

cation

(cat' eye on) An ion with one or more positive charges. (Contrast with anion.)

cation exchange

The process in soil by which cations bound to soil particles are released from the particles and made available to plant roots in soil water through the binding of hydrogen ions to the soil particles.

CCK

See cholecystokinin.

Cdk

See cyclin-dependent kinase.

cDNA

See complementary DNA.

cDNA library

A collection of complementary DNAs derived from mRNAs of a particular tissue at a particular time in the life cycle of an organism.

cecum

(see' cum) [L. blind] A blind branch off the large intestine. In many nonruminant mammals, the cecum contains a colony of microorganisms that contribute to the digestion of food.

cell

The simplest structural unit of a living organism. In multicellular organisms, many individual cells serve as the building blocks of tissues and organs.

cell adhesion

The binding of one cell to another, often mediated by noncovalent forces.

cell body

The portion of the neuron that contains the nucleus and gives rise to dendrites and an axon.

cell cycle checkpoints

Points of transition between different phases of the cell cycle, which are regulated by cyclins and cyclin-dependent kinases (Cdk's).

cell cycle

The stages through which a cell passes between one mitotic division and the next. Includes all stages of interphase and mitosis. (See mitosis.)

cell fate

The type of cell that an undifferentiated cell in an embryo will become in the adult.

cell junctions

Specialized structures associated with the plasma membranes of epithelial cells. Some contribute to cell adhesion, others to intercellular communication.

cell membrane

The membrane that surrounds the cell, regulating the entry and exit of molecules and ions. Every cell has a cell membrane, and it is also called the plasma membrane.

cell potency

In multicellular organisms, an undifferentiated cell's potential to become a cell of a specific type. (See multipotent, pluripotent, totipotent.)

cell recognition

Binding of cells to one another mediated by membrane proteins or carbohydrates.

cell theory

States that cells are the basic structural and physiological units of all living organisms, and that all cells come from preexisting cells.

cell wall

A relatively rigid structure that encloses cells of plants, fungi, many protists, and most prokaryotes, and which gives these cells their shape and limits their expansion in hypotonic media.

cellular immune response

Immune system response mediated by T cells and directed against parasites, fungi, intracellular viruses, and foreign tissues (grafts). (Contrast with humoral immune response.)

cellular respiration

The catabolic pathways by which electrons are removed from various molecules and passed through intermediate electron carriers to O_2 , generating H_2O and releasing energy.

cellular respiration

The catabolic pathways by which electrons are removed from various molecules and passed through intermediate electron carriers to O_2 , generating H_2O and releasing energy.

cellular specialization

In multicellular organisms, the division of labor such that different cell types become responsible for different functions (e.g., reproduction or digestion) within the organism.

cellulose

(sell' you lowss) A straight-chain polymer of glucose molecules, used by plants as a structural supporting material.

central dogma

The premise that information flows from DNA to RNA to polypeptide (protein).

central nervous system (CNS)

That portion of the nervous system that is the site of most information processing, storage, and retrieval; in vertebrates, the brain and spinal cord. (Contrast with peripheral nervous system.)

central vacuole

In plant cells, a large organelle that stores the waste products of metabolism and

maintains turgor.

centriole

(sen' tree ole) A paired organelle that helps organize the microtubules in animal and protist cells during nuclear division.

centromere

(sen' tro meer) [Gk. *centron*: center + *meros*: part] The region where sister chromatids join.

centrosome

(sen' tro soam) The major microtubule organizing center of an animal cell.

cephalization

(sef ah luh zay' shun) [Gk. *kephale*: head] The evolutionary trend toward increasing concentration of brain and sensory organs at the anterior end of the animal.

cerebellum

(sair uh bell' um) [L. diminutive of *cerebrum*: brain] The brain region that controls muscular coordination; located at the anterior end of the hindbrain.

cerebral cortex

The thin layer of gray matter (neuronal cell bodies) that overlies the cerebrum.

cerebral hemispheres

The bilateral divisions of the cerebrum.

cerebrum

(su ree' brum) [L. brain] The dorsal anterior portion of the forebrain, making up the largest part of the brain of mammals; the chief coordination center of the nervous system and the major information-processing areas of the vertebrate brain consists of two cerebral hemispheres.

cervix

(sir' vix) [L. neck] The opening of the uterus into the vagina.

channel protein

An integral membrane protein that forms an aqueous passageway across the membrane in which it is inserted and through which specific solutes may pass.

chaperone

A protein that guards other proteins by counteracting molecular interactions that threaten their three-dimensional structure.

character displacement

An evolutionary phenomenon in which species that compete for the same limiting resources diverge in morphology and/or behavior.

character

In genetics, an observable feature, such as eye color. (Contrast with trait.)

chemical bond

An attractive force stably linking two atoms.

chemical equilibrium

See equilibrium.

chemical evolution

The theory that life originated through the chemical transformation of inanimate substances.

chemical reaction

The change in the composition or distribution of atoms of a substance with consequent alterations in properties.

chemical synapse

Neural junction at which neurotransmitter molecules released from a presynaptic cell induce changes in a postsynaptic cell. (Contrast with electrical synapse.)

chemically gated channel

A type of membrane channel that opens or closes depending on the presence or absence of a specific molecule that binds either to the channel protein itself or to a separate receptor that alters the three-dimensional shape of the channel protein.

chemiosmosis

Formation of ATP in mitochondria and chloroplasts, resulting from a pumping of protons across a membrane (against a gradient of electrical charge and of pH), followed by the return of the protons through a protein channel with ATP synthase activity.

chemoautotroph

An organism that obtains energy by oxidizing inorganic substances, using some of that energy to fix carbon. Also known as a chemolithotroph. (Contrast with chemoheterotroph, photoautotroph, photoheterotroph.)

chemoheterotroph

An organism that must obtain both carbon and energy from organic substances. (Contrast with chemoautotroph, photoautotroph, photoheterotroph.)

chemoreceptor

A receptor protein that binds to specific molecules (such as odorant molecules or pheromones) in the environment.

chemosynthesis

The use of energy from inorganic chemical compounds by archaea and bacteria to fix CO_2 and produce carbohydrates using the Calvin cycle.

chi-square goodness-of-fit

A statistical test used to assess whether the frequencies of observations in different

categories are consistent with an hypothesized frequency distribution.

chiasma

(kie az' muh) (plural: chiasmata) [Gk. cross] An X-shaped connection between paired homologous chromosomes in prophase I of meiosis. A chiasma is the visible manifestation of crossing over between homologous chromosomes.

chief cells

One of three types of secretory cell found in the gastric pits of the stomach wall. Chief cells secrete the protein-digesting enzyme pepsin. (See parietal cells.)

chitin

(kye' tin) [Gk. *kiton*: tunic] The characteristic tough but flexible organic component of the exoskeleton of arthropods, consisting of a complex, nitrogen-containing polysaccharide. Also found in cell walls of fungi.

chlorophyll

(klor' o fill) [Gk. *kloros*: green + *phyllon*: leaf] Any of several green pigments associated with chloroplasts or with certain bacterial membranes; responsible for trapping light energy for photosynthesis.

chloroplast

[Gk. *kloros*: green + *plast*: a particle] An organelle bounded by a double membrane containing the enzymes and pigments that perform photosynthesis. Chloroplasts occur only in eukaryotes.

choanocyte

(ko' an uh site) The collared, flagellated feeding cells of sponges.

cholecystokinin (CCK)

(ko' luh sis tuh kai' nin) A hormone produced and released by the lining of the duodenum when it is stimulated by undigested fats and proteins. It stimulates the gallbladder to release bile and slows stomach activity.

chorion

(kor' ee on) [Gk. *chorion*: afterbirth] The outermost of the membranes protecting mammal, bird, and reptile embryos; in mammals it forms part of the placenta.

chromatin

The nucleic acid–protein complex that makes up eukaryotic chromosomes.

chromosomal mutation

Loss of or changes in position/direction of a DNA segment on a chromosome.

chromosome

(krome' o sowm) [Gk. *kroma*: color + *soma*: body] In bacteria and viruses, the DNA molecule that contains most or all of the genetic information of the cell or virus. In eukaryotes, a structure composed of DNA and proteins that bears part of the genetic information of the cell.

chylomicrons

(ky low my' cron) Particles of lipid coated with protein, produced in the gut from dietary fats and secreted into the extracellular fluids.

chyme

(kime) [Gk. *kymus*: juice] Created in the stomach; a mixture of ingested food with the digestive juices secreted by the salivary glands and the stomach lining.

cilia

(sil' ee ah) (singular: cilium) [L. eyelashes] Hairlike organelle used for locomotion by many unicellular organisms and for moving water and mucus by many multicellular organisms. Generally shorter than flagella.

circadian rhythm

(sir kade' ee an) [L. *circa*: approximately + *dies*: day] A rhythm of growth or activity that recurs about every 24 hours.

circulatory system

A physiological system consisting of a muscular pump (heart), a fluid (blood or hemolymph), and a series of conduits (blood vessels) that transports materials around the body.

cis-trans isomers

In molecules with a double bond (typically between two carbon items), identifies on which side of the double bond similar atoms or functional groups are found. If they are on the same side, the molecule is a *cis* isomer; in a *trans* isomer, similar atoms are on opposite sides of the double bond. (See isomers.)

clade

[Gk. *klados*: branch] A monophyletic group made up of an ancestor and all of its descendants.

class

A group of things defined by particular attributes.

class I MHC proteins

Cell surface proteins that participate in the cellular immune response directed against virus-infected cells.

class II MHC proteins

Cell surface proteins that participate in the cell–cell interactions (of T-helper cells, macrophages, and B cells) of the humoral immune response.

class switching

Occurs when a B cell changes the immunoglobulin class it synthesizes (e.g., a B cell making IgM switches to making IgG).

cleavage

The first few cell divisions of an animal zygote. (See *also* complete cleavage,

incomplete cleavage.)

climate

The long-term average atmospheric conditions (temperature, precipitation, humidity, wind direction and velocity) at a particular place over longer time (years to millennia). (Contrast with weather.)

climax community

The final stage of succession; a community that is capable of perpetuating itself under local climatic and soil conditions and persists for a relatively long time.

clinal variation

[Gk. *klinein*: to lean] Gradual change in the phenotype of a species over a geographic gradient.

clonal deletion

Inactivation or destruction of lymphocyte clones that would produce immune reactions against the animal's own body.

clonal lineages

Asexually reproduced groups of nearly identical organisms.

clonal selection

Mechanism by which exposure to antigen results in the activation of selected T- or B-cell clones, resulting in an immune response.

clone

[Gk. *klon*: twig, shoot] (1) Genetically identical cells or organisms produced from a common ancestor by asexual means. (2) To produce many identical copies of a DNA sequence by its introduction into, and subsequent asexual reproduction of, a cell or organism.

closed circulatory system

Circulatory system in which the circulating fluid is contained within a continuous system of vessels. (Contrast with open circulatory system.)

clumped dispersion

The spatial arrangement of individuals within a population, characterized by clumped spatial patterns. (Compare with random dispersion, regular (uniform) dispersion.)

CO (CONSTANS)

Gene coding for a transcription factor that activates the synthesis of florigen (FT); involved in the induction of flowering.

co-repressor

In the regulation of bacterial operons, a molecule that binds to the repressor, causing it to change shape and bind to the operator, thereby inhibiting transcription.

coastal zone

The marine life zone that extends from the shoreline to the edge of the continental shelf. Characterized by relatively shallow, well-oxygenated water and variable temperatures and salinities.

coccus

(kock' us) (plural: cocci) [Gk. *kokkos*: berry, pit] Any of various spherical or spheroidal bacteria.

cochlea

(kock' lee uh) [Gk. *kokhlos*: snail] A spiral tube in the inner ear of vertebrates; it contains the sensory cells involved in hearing.

codominance

A condition in which two alleles at a locus produce different phenotypic effects and both effects appear in heterozygotes.

codon

Three nucleotides in messenger RNA that direct the placement of a particular amino acid into a polypeptide chain. (Contrast with anticodon.)

coelomate

Possessing a coelom.

coenocytic

(seen' a sit ik) [Gk. *koinos*: common + *kytos*: container] Referring to the condition, found in some fungal hyphae, of "cells" containing many nuclei but enclosed by a single plasma membrane. Results from nuclear division without cytokinesis.

coevolution

Evolutionary process in which an adaptation in one species leads to the evolution of an adaptation in a species with which it interacts.

cohesion

The tendency of molecules (or any substances) to stick together.

cohort life table

A life table in which the fate of a group of individuals born during the same time frame (a cohort) is followed from birth to death.

cold-hardening

A process by which plants can acclimate to cooler temperatures; requires repeated exposure to cool temperatures over many days.

coleoptile

A sheath that surrounds and protects the shoot apical meristem and young primary leaves of a grass seedling as they move through the soil.

collagen

[Gk. *kolla*: glue] A fibrous protein found extensively in bone and connective tissue.

collecting duct

In vertebrates, a tubule that receives urine produced in the nephrons of the kidney and delivers that fluid to the ureter for excretion.

collenchyma

(cull eng' kyma) [Gk. *kolla*: glue + *enchyma*: infusion] A type of plant cell, living at functional maturity, which lends flexible support by virtue of primary cell walls thickened at the corners. (Contrast with parenchyma, sclerenchyma.)

colon

[Gk. *kolon*] The portion of the gut between the small intestine and the anus. Also called the large intestine.

commensalism

[L. *com*: together + *mensa*: table] A type of positive interaction in which one species benefits from the interaction while the other is unaffected. (Contrast with amensalism, competition, mutualism.)

communication

A signal from one organism (or cell) that alters the functioning or behavior of another organism (or cell).

community

A group of species living together at the same place and time.

community function

The way a community works as measured by metrics such as plant productivity or stability.

community structure

The set of characteristics or patterns that describe a community, including the number, composition, and abundance of species.

compact bone

A type of bone with a solid, hard structure. (Contrast with cancellous bone.)

companion cell

In angiosperms, a specialized cell found adjacent to a sieve tube element.

comparative experiment

Experimental design in which data from various unmanipulated samples or populations are compared, but in which variables are not controlled or even necessarily identified. (Contrast with controlled experiment.)

comparative genomics

Computer-aided comparison of DNA sequences between different organisms to reveal genes with related functions.

comparator

In a regulatory system, the mechanism for comparing a feedback variable to a set point to generate command signals to effector organs.

competition

A nontrophic interaction in which two or more species overlap in the use of at least some of the same required limiting resources, negatively affecting their growth, reproduction, and/or survival. (Contrast with amensalism, commensalism, mutualism.)

competitive coexistence

The ability of species to coexist with one another despite sharing limiting resources. (Contrast with competitive exclusion.)

competitive exclusion

A result of competition between species for resources, in which one species completely eliminates the other from a given habitat. (Contrast with competitive coexistence.)

competitive inhibitor

A nonsubstrate that binds to the active site of an enzyme and thereby inhibits binding of its substrate. (Contrast with noncompetitive inhibitor.)

complement system

A group of eleven proteins that play a role in some reactions of the immune system. The complement proteins are not immunoglobulins.

complementary base pairing

The AT (or AU), TA (or UA), CG, and GC pairing of bases in double-stranded DNA, in transcription, and between tRNA and mRNA.

complementary diet

A mixture of foods that supplies all essential nutrients.

complementary DNA (cDNA)

DNA formed by reverse transcriptase acting with an RNA template; essential intermediate in the reproduction of retroviruses; used as a tool in recombinant DNA technology; lacks introns.

complete cleavage

Pattern of cleavage that occurs in eggs that have little yolk. Early cleavage furrows divide the egg completely, and the blastomeres are of similar size. (Contrast with incomplete cleavage.)

complete gut

A gut with an entrance and a separate exit.

complete metamorphosis

A change of state during the life cycle of an organism in which the body is almost

completely rebuilt to produce an individual with a very different body form.
Characteristic of insects such as butterflies, moths, beetles, ants, wasps, and flies.

complex ions

Groups of covalently bonded atoms that carry an electric charge (e.g., NH_4^+ , the ammonium ion).

complex life cycle

In reference to parasitic species, a life cycle that requires more than one host to complete.

composite transposon

Two transposable elements located near one another that transpose together and carry the intervening DNA sequence with them. (See transposable element.)

compound

(1) A substance made up of atoms of more than one element. (2) Made up of many units, as in the **compound eyes** of arthropods.

concentration gradient

A difference in concentration of an ion or other chemical substance from one location to another, often across a membrane. (See active transport, facilitated diffusion.)

concerted evolution

The common evolution of a family of repeated genes, such that changes in one copy of the gene family are replicated in other copies of the gene family, and thus evolve "in concert." (See biased gene conversion, unequal crossing over.)

condensation reaction

A chemical reaction in which two molecules become connected by a covalent bond and a molecule of water is released ($\text{AH} + \text{BOH} \rightarrow \text{AB} + \text{H}_2\text{O}$.) (Contrast with hydrolysis reaction.)

conditional mutation

A mutation that results in a characteristic phenotype only under certain environmental conditions.

conditioned reflex

A form of associative learning first described by Ivan Pavlov, in which a natural response (such as salivation in response to food) becomes associated with a normally unrelated stimulus (such as the sound of a bell or a metronome).

conduction

The transfer of heat from one object to another through direct contact.

cone cells

In the vertebrate retina, photoreceptor cells responsible for color vision.

cone

In conifers, a reproductive structure consisting of spore-bearing scales extending from a central axis. (Contrast with strobilus.)

confidence interval

A numerical interval that is calculated to contain the true value of some parameter of interest at a stated probability level. For example, a **95% confidence interval** contains the true value of some parameter of interest in 95% of cases.

conidium

(ko nid' ee um) (plural: conidia) [Gk. *konis*: dust] A type of haploid fungal spore borne at the tips of hyphae, not enclosed in sporangia.

conjugation

(kon ju gay' shun) [L. *conjugare*: yoke together] (1) A process by which DNA is passed from one cell to another through a conjugation tube, as in bacteria. (2) A nonreproductive sexual process by which *Paramecium* and other ciliates exchange genetic material.

connective tissue

A type of tissue that connects or surrounds other tissues; its cells are embedded in a collagen-containing matrix. One of the four major tissue types in multicellular animals, including cartilage, bone, blood, and fat.

connexon

In a gap junction, a protein channel linking adjacent animal cells.

conservation biology

An integrative scientific discipline that relies on principles of ecology, economics, social science, and policy to protect and manage Earth's biodiversity.

conspecifics

Individuals of the same species.

constant region

The portion of an immunoglobulin molecule whose amino acid composition determines its class and does not vary among immunoglobulins in that class. (Contrast with variable region.)

constitutive

Always present; produced continually at a constant rate. (Contrast with inducible.)

constitutive proteins

Proteins that an organism produces all the time, and at a relatively constant rate.

consumption efficiency

The proportion of available biomass that is ingested by consumers.

continental drift

The gradual movements of the world's continents that have occurred over billions of years.

continuous variables

Variables that can take on a continuous range of values.

contraception

Birth control methods that prevent fertilization or implantation (conception).

contractile vacuole

(kon trak' tul) A specialized vacuole that collects excess water taken in by osmosis, then contracts to expel the water from the cell.

controlled experiment

An experiment in which a sample is divided into groups whereby experimental groups are exposed to manipulations of an independent variable while one group serves as an untreated control. The data from the various groups are then compared to see if there are changes in a dependent variable as a result of the experimental manipulation. (Contrast with comparative experiment.)

controlled system

A set of components in a physiological system that is controlled by commands from a regulatory system. (Contrast with regulatory system.)

convection

The transfer of heat to or from a surface via a moving stream of air or fluid.

convergent evolution

Independent evolution of similar features from different ancestral traits.

convergent extension

Movements of cells in the sea urchin blastula that form the archenteron. These cells elongate, flatten, and interdigitate to form a tubular structure.

convolutions

Foldings of the vertebrate brain's cerebral cortex into ridges called gyri and valleys called sulci. The level of cortical convolution increases taxonomically and is especially extensive in humans.

coprophagy

The consumption of feces.

copulation

Reproductive behavior that results in a male depositing sperm in the reproductive tract of a female.

coral bleaching

The loss of color in coral colonies, usually because of the loss or decline of symbiotic zooxanthellae.

Coriolis effect

The deflection of air or water as a result of differences in Earth's rotational speed at different latitudes.

cork cambium

[L. *cambiare*: to exchange] In plants, a lateral meristem that produces secondary growth, mainly in the form of waxy-walled protective cells, including some of the cells that become bark.

cornea

The clear, transparent tissue that covers the eye and allows light to pass through to the retina.

coronary artery

An artery that serves the cardiac muscles.

coronary thrombosis

A blood clot in a blood vessel of the heart.

corpora allata

The insect endocrine gland that secretes juvenile hormone.

corpora cardiaca

An insect endocrine gland that secretes PTTH.

corpus luteum

(kor' pus loo' tee um) (plural: corpora lutea) [L. yellow body] A structure formed from a follicle after ovulation; produces hormones important to the maintenance of pregnancy.

correlation coefficient

A measure of the strength of relationship between two quantitative variables, ranging from -1 (a perfect negative relationship) to 1 (a perfect positive relationship).

cortex

[L. *cortex*: covering, rind] (1) In plants, the tissue between the epidermis and the vascular tissue of a stem or root. (2) In animals, the outer tissue of certain organs, such as the adrenal gland (adrenal cortex) and the brain (cerebral cortex).

corticosteroids

Steroid hormones produced and released by the cortex of the adrenal gland.

corticotropin

A tropic hormone produced by the anterior pituitary hormone that stimulates cortisol release from the adrenal cortex. Also called adrenocorticotrophic hormone (ACTH).

corticotropin-releasing hormone (CRH)

A hormone produced by the hypothalamus that controls the release of cortisol from the anterior pituitary.

cortisol

A corticosteroid that mediates stress responses.

cost–benefit approach

An approach to evolutionary studies that assumes an animal has a limited amount of time and energy to devote to each of its activities, and that each activity has fitness costs as well as benefits. (See *also* tradeoff.)

cotyledon

(kot' ul lee' dun) [Gk. *kotyledon*: hollow space] A “seed leaf.” An embryonic organ that stores and digests reserve materials; may expand when seed germinates.

countercurrent flow

An arrangement that promotes the maximum exchange of heat, or of a diffusible substance, between two fluids by having the fluids flow in opposite directions through parallel vessels close together.

countercurrent heat exchange

In “hot” fishes, an adaptation of the circulatory system such that arterial blood flowing into the muscles is warmed by venous blood flowing out of the muscles, thereby conserving body heat by countercurrent exchange.

countercurrent multiplier

The mechanism that increases the concentration of the interstitial fluid in the mammalian kidney through countercurrent flow in the loops of Henle and selective permeability and active transport of ions by segments of the loops of Henle.

coupled human–natural system ecology

The practice of encouraging biodiversity and sustainability in systems where humans and nature are intricately linked.

coupled transporters

Membrane proteins that transport two substances across a membrane, often with the transport of one driving the transport of another.

covalent bond

Chemical bond based on the sharing of electrons between two atoms.

CpG islands

DNA regions rich in C residues adjacent to G residues. Especially abundant in promoters, these regions are where methylation of cytosine usually occurs.

cranial nerves

The 12 pairs of nerves that go directly from the brain to different parts of the body without going down the spinal cord.

crassulacean acid metabolism (CAM)

A metabolic pathway enabling the plants that possess it to store carbon dioxide at night and then perform photosynthesis during the day with stomata closed.

creatine phosphate (CP)

A phosphorylated creatine molecule that is abundant in skeletal muscle and can shuttle high energy phosphate from mitochondria to myofibrils.

CRISPR

In archaea, clustered regularly interspaced short palindromic sequences in DNA that are adjacent to sequences from invading viruses. When the two sequences are transcribed, the RNA binds a complementary RNA that binds a nuclease, Cas9, that can cleave and inactivate the genome of the invading virus. This mechanism can be adapted for inactivating and mutating any gene.

critical period

See sensitive period.

crop

A simple food storage sac, the first of two stomachlike organs in many animals (including reptiles, earthworms, and various insects). (See *also* gizzard.)

crossing over

The mechanism by which linked genes undergo recombination. In general, the term refers to the reciprocal exchange of corresponding segments between two homologous chromatids.

crosstalk

Interactions between different signal transduction pathways.

crustose

A growth form of organisms, such as lichens, in which the organism forms a thin, close, tight bond with the surface of a rock, tree, or other object.

crypsis

[Gk. *kryptos*: hidden] The resemblance of an organism to some part of its environment, which helps it to escape detection by enemies.

cryptochromes

[Gk. *kryptos*: hidden + *kroma*: color] Photoreceptors mediating some blue-light effects in plants and animals.

ctene

(teen) [Gk. *cteis*: comb] In ctenophores, a comblike row of cilia-bearing plates. Ctenophores move by beating the cilia on their eight ctenes.

cumulus

A thick gelatinous layer that protects a mammalian ovum.

cupula

Gelatinous swelling in the semicircular canals of the vestibular system. A cupula encloses hair cell stereocilia that react to shifting fluid in the canal ducts.

cuticle

(1) In plants, a waxy layer on the outer body surface that retards water loss. (2) In ecdysozoans, an outer body covering that provides protection and support and is periodically molted.

cyclic AMP

See cAMP.

cyclic electron transport

In photosynthetic light reactions, the flow of electrons that produces ATP but not NADPH or O₂.

cyclin

A protein that activates a cyclin-dependent kinase, bringing about transitions in the cell cycle.

cyclin-dependent kinase (Cdk)

A protein kinase whose target proteins are involved in transitions in the cell cycle and which is active only when complexed with additional protein subunits, called cyclins.

cytokine

A regulatory protein made by immune system cells that affects other target cells in the immune system.

cytokinesis

(sy' toe kine ee' sis) [Gk. *kytos*: container + *kinein*: to move] The division of the cytoplasm of a dividing cell. (Contrast with mitosis.)

cytokinin

(sy' toe kine' in) A member of a class of plant growth substances that plays roles in senescence, cell division, and other phenomena.

cytoplasm

The contents of the cell, excluding the nucleus.

cytoplasmic determinants

In animal development, gene products whose spatial distribution may determine such things as embryonic axes.

cytoplasmic segregation

The asymmetrical distribution of cytoplasmic determinants in a developing animal embryo.

cytoplasmic streaming

The flow of cytoplasm around fungal and plant cells.

cytosine (C)

(site' oh seen) A nitrogen-containing base found in DNA and RNA.

cytoskeleton

The network of microtubules and microfilaments that gives a eukaryotic cell its shape and its capacity to arrange its organelles and to move.

cytotoxic T (T_C)

cells Cells of the cellular immune system that recognize and directly eliminate virus-infected cells. (Contrast with T-helper cells.)

D

DAG

See diacylglycerol.

daily torpor

A daily reduction in metabolic rate and body temperature to conserve energy.

dalton (DA)

A measure of mass for atoms equal to the atomic mass unit.

data

Quantified observations about a system under study.

daughter chromosomes

During mitosis, the separated chromatids from the beginning of anaphase onward.

dead space

The lung volume that fails to be ventilated with fresh air (because the lungs are never completely emptied during exhalation).

declarative memory

Memory of people, places, events, and things that can be consciously recalled and described.

decomposer

See detritivore.

decomposition

The physical and chemical breakdown of detritus by bacteria and detritivores, leading to the release of nutrients and energy.

deductive logic

Logical thought process that starts with a premise believed to be true then predicts what facts would also have to be true to be compatible with that premise. (Contrast with inductive logic.)

defensin

A type of protein made by phagocytes that kills bacteria and enveloped viruses by insertion into their plasma membranes.

deficiency disease

A condition (e.g., scurvy and beriberi) caused by chronic lack of any essential nutrient.

delayed hypersensitivity

Allergic response in which a T cell clone resulting from binding to an antigen-presenting cell releases cytokines over a period of hours to days, resulting in such effects as inflammation and rash. (Contrast with immediate hypersensitivity.)

deletion

A mutation resulting from the loss of a continuous segment of a gene or chromosome. Such mutations almost never revert to wild type. (Contrast with duplication, point mutation.)

demethylase

An enzyme that catalyzes the removal of the methyl group from cytosine, reversing DNA methylation.

demographic stochasticity

Fluctuations in population size as the result of random differences among individuals in reproduction and survival.

demography

The study of how births, deaths, immigration, and emigration affect population changes over time.

denaturation

Loss of activity of an enzyme or nucleic acid molecule as a result of structural changes induced by heat or other means.

dendrites

[Gk. *dendron*: tree] Branching fibers (processes) of a neuron. Dendrites are usually relatively short compared with the axon, and commonly carry information to the neuronal cell body.

denitrifiers

Bacteria that release nitrogen to the atmosphere as nitrogen gas (N_2).

density-dependent

Factors such as limiting resources, predators, or pathogens that have a negative effect on population size as a consequence of the density of individuals. (Contrast with density-independent.)

density-independent

Factors such as the physical environment that have a negative effect on population

size independent of the density of the population. (Contrast with density-dependent.)

dentine

The layer of dense bony material beneath the enamel of the tooth.

deoxyribose

A five-carbon sugar found in nucleotides and DNA.

depolarization

A change in the resting potential across a membrane so that the inside of the cell becomes less negative, or even positive, compared with the outside of the cell. (Contrast with hyperpolarization.)

deprivation experiments

Raising an animal in an environment devoid of behavioral models from which it could learn a species specific behavior to see if the behavior is still expressed.

derived trait

A trait that differs from the ancestral trait. (Contrast with synapomorphy.)

dermal tissue system

The system of cells that forms the outer covering of a plant, consisting of epidermis in the young plant and periderm in a plant with extensive secondary growth. (Contrast with ground tissue system, vascular tissue system.)

descent with modification

Darwin's premise that all species share a common ancestor and have diverged from one another gradually over time.

descriptive statistics

Quantitative measures that describe general patterns in data.

desmosome

(dez' mo sowm) [Gk. *desmos*: bond + *soma*: body] An adhering junction between animal cells.

desmotubule

A membrane extension connecting the endoplasmic reticulum of two plant cells that traverses the plasmodesma.

determinate growth

A growth pattern in which the growth of an organism or organ ceases when an adult state is reached; characteristic of most animals and some plant organs. (Contrast with indeterminate growth.)

determination

In development, the process whereby the fate of an embryonic cell or group of cells (e.g., to become epidermal cells or neurons) is set (becomes **determined**).

detritivore

(di try' ti vore) [L. *detritus*: worn away + *vorare*: to devour] An organism that obtains its energy from the dead bodies or waste products (**detritus**) of other organisms, releasing nutrients and energy. (Contrast with carnivore, herbivore, omnivore.)

development

The process by which a multicellular organism, beginning with a single cell, goes through a series of changes, taking on the successive forms that characterize its life cycle.

diacylglycerol (DAG)

In hormone action, the second messenger produced by hydrolytic removal of the head group of certain phospholipids.

diaphragm

(dye' uh fram) [Gk. *diaphrassein*: barricade] (1) A sheet of muscle that separates the thoracic and abdominal cavities in mammals; responsible for breathing. (2) A method of birth control in which a sheet of rubber is fitted over the woman's cervix, blocking the entry of sperm.

diastole

(dye ass' toll ee) [Gk. dilation] The portion of the cardiac cycle when the heart muscle relaxes. (Contrast with systole.)

dichotomous

(dye cot' oh mus) [Gk. *dichot*: split in two + *tomia*: removed] A branching pattern in which the shoot divides at the apex producing two equivalent branches that subsequently never overlap.

diencephalon

The portion of the vertebrate forebrain that develops into the thalamus and hypothalamus.

differentiation

The process whereby originally similar cells follow different developmental pathways; the actual expression of determination.

diffusion

Random movement of molecules or other particles, resulting in even distribution of the particles when no barriers are present. (Contrast with active transport, diffusion.)

digestive vacuole

In protists, an organelle specialized for digesting food ingested by endocytosis.

dihybrid cross

A mating in which the parents differ with respect to the alleles of two loci of interest.

dikaryon

(di care' ee ahn) [Gk. *di*: two + *karyon*: kernel] A cell or organism carrying two genetically distinguishable nuclei. Common in fungi.

dioecious

(die eesh' us) [Gk. *di*: two + *oikos*: house] Pertaining to organisms in which the two sexes are "housed" in two different individuals, so that eggs and sperm are not produced in the same individuals. Examples: humans, fruit flies, date palms. (Contrast with monoecious.)

diploblastic

Having a body derived from only two embryonic cell layers (ectoderm and endoderm, but no mesoderm) (Contrast with monoblastic, triploblastic.)

diploid

(dip' loid) [Gk. *diplos*: double] Having a chromosome complement consisting of two copies (homologs) of each chromosome. Designated $2n$. (Contrast with haploid.)

direct development

Pattern of development (notably among insects) in which hatchlings look like miniature versions of adults. (Contrast with metamorphosis.)

direct fitness

That component of fitness resulting from an organism producing its own offspring. (Contrast with inclusive fitness.)

direct interaction

An interaction that occurs between two species, such as predation, competition, or a positive interaction. (Compare with indirect interaction.)

directional selection

Selection in which phenotypes at one extreme of the population distribution are favored. (Contrast with disruptive selection, stabilizing selection.)

disaccharide

A carbohydrate made up of two monosaccharides (simple sugars).

discoidal cleavage

In animal development, a type of incomplete cleavage that is common in fishes, reptiles, and birds, the eggs of which contain a dense yolk mass.

discrete variables

Quantitative variables that take on only whole number values.

dispersal

Movement of individuals into (immigration) or out of (emigration) an existing population.

dispersion patterns

The spatial arrangement of individuals in space within a population. (See regular,

random, and clumped patterns.)

disruptive selection

Selection in which phenotypes at both extremes of the population distribution are favored. (Contrast with directional selection, stabilizing selection.)

dissociation constant (K_D)

A type of equilibrium constant measuring the tendency of a two substances that are bound together to separate into the two smaller components. In cell signaling, the two substances are a ligand and receptor.

distal convoluted tubule

The portion of a renal tubule from where it reaches the renal cortex, just past the loop of Henle to where it joins a collecting duct. (Compare with proximal convoluted tubule.)

disturbance

An abiotic event that physically or chemically injures or kills some individuals, creating opportunities for other individuals to grow and/or reproduce. (Contrast with stress.)

disulfide bridge

The covalent bond between two sulfur atoms ($-S-S-$) linking two molecules or remote parts of the same molecule.

DNA (deoxyribonucleic acid)

The fundamental hereditary material of all living organisms. In eukaryotes, stored primarily in the cell nucleus. A nucleic acid using deoxyribose rather than ribose.

DNA fingerprint

An individual's unique pattern of allele sequences, commonly short tandem repeats and single nucleotide polymorphisms.

DNA helicase

An enzyme that unwinds the double helix.

DNA ligase

Enzyme that unites broken DNA strands during replication and recombination.

DNA methyltransferase

An enzyme that catalyzes the methylation of DNA.

DNA microarray

A small glass or plastic square onto which thousands of single-stranded DNA sequences are fixed so that hybridization of cell-derived RNA or DNA to the target sequences can be performed.

DNA polymerase

Any of a group of enzymes that catalyze the formation of DNA strands from a DNA

template.

DNA replication

The creation of a new strand of DNA in which DNA polymerase catalyzes the exact reproduction of an existing (template) strand of DNA.

DNA testing

In human genetics, the determination of genotype by analysis of DNA sequence.

domain

(1) An independent structural element within a protein. Encoded by recognizable nucleotide sequences, a domain often folds separately from the rest of the protein. Similar domains can appear in a variety of different proteins across phylogenetic groups (e.g., “homeobox domain,” “calcium-binding domain”). (2) In phylogenetics, the three monophyletic branches of life (Bacteria, Archaea, and Eukarya).

dominance

In genetics, the ability of one allelic form of a gene to determine the phenotype of a heterozygous individual in which the homologous chromosomes carry both it and a different (recessive) allele. (Contrast with recessive.)

dormancy

A condition in which normal activity is suspended, as in some spores, seeds, and buds.

dorsal

[L. *dorsum*: back] Toward or pertaining to the back or upper surface. (Contrast with ventral.)

dorsal lip

In amphibian embryos, the dorsal segment of the blastopore. Also called the organizer, this region directs the development of nearby embryonic regions.

double fertilization

In angiosperms, a process in which the nuclei of two sperm fertilize one egg. One sperm's nucleus combines with the egg nucleus to produce a zygote, while the other combines with the same egg's two polar nuclei to produce the first cell of the triploid endosperm (the tissue that will nourish the growing plant embryo).

double helix

Refers to DNA and the (usually right-handed) coil configuration of two complementary, antiparallel strands.

duodenum

(do' uh dee' num) The beginning portion of the vertebrate small intestine. (See *also* ileum, jejunum.)

duplication

A mutation in which a segment of a chromosome is duplicated, often by the

attachment of a segment lost from its homolog. (Contrast with deletion.)

E

early successional species

See pioneer species.

easterlies

Prevailing winds that blow from east to west at high latitudes. (Compare with westerlies.)

ecdysone

(eck die' sone) [Gk. *ek*: out of + *dyo*: to clothe] In insects, a hormone that induces molting.

ecology

[Gk. *oikos*: house] The scientific study of the interrelationships of organisms with their living (biotic) and nonliving (abiotic) environments.

ecosystem

(eek' oh sis tum) The organisms of a particular community together with the physical and chemical environment in which they live.

ecosystem engineering species

Species that create, modify, or maintain physical habitat for themselves and other species, and can be keystone or foundation species as well.

ecosystem science

A branch of ecology that considers how energy flows and nutrients cycle through communities.

ecosystem values

Measures of the economic and biophysical values of ecosystem services to humans.

ecosystems services

Benefits that humans obtain from ecosystems such as natural products, protective and regulating services, and recreational, aesthetic, and spiritual enrichment.

ectoderm

[Gk. *ektos*: outside + *derma*: skin] The outermost of the three embryonic germ layers first delineated during gastrulation. Gives rise to the skin, sense organs, and nervous system.

ectomycorrhizae

Mutualistic fungi that cover the roots of plants and assist in the uptake of water and minerals from the soil by the plant.

ectoparasite

A parasite that lives on the surface of its host organism. (Compare with

endoparasite.)

ectotherm

[Gk. *ektos*: outside + *thermos*: heat] An animal that is dependent on external heat sources for regulating its body temperature (Contrast with endotherm.)

edge effects

Abiotic and biotic changes to the edge of a habitat brought about by habitat fragmentation.

effective population size

The number of individuals within a population that can contribute offspring to the next generation of the population.

effector

A component of a physiological system that responds to information by *effecting* changes (making change happen) in the internal environment; examples include muscles and the secretory cells of the digestive tract.

effector cells

In cellular immunity, B cells and T cells that attack an antigen, either by secreting antibodies that bind to the antigen or by releasing molecules that destroy any cell bearing the antigen.

effector mechanisms

Adaptations that enable an organism to alter its physiological or behavioral state.

effector protein

In cell signaling, a protein responsible for the cellular response to a signal transduction pathway.

efferent

(ef' ur unt) [L. *ex*: out + *ferre*: to bear] Carrying outward or away from, as in neurons that carry impulses outward from the central to the peripheral nervous system (**efferent neurons**), or a blood vessel that carries blood away from a structure (**efferent arterioles**). (Contrast with afferent.)

egg

In all sexually reproducing organisms, the female gamete; in birds, reptiles, and some other vertebrates, a structure within which early embryonic development occurs. (See *also* amniote egg, ovum.)

ejaculatory duct

The duct that carries semen from the seminal vesicle to the urethra.

electrical synapse

A type of synapse at which action potentials spread directly from presynaptic cell to postsynaptic cell. (Contrast with chemical synapse.)

electrocardiogram (ECG or EKG)

A graphic recording of electrical potentials from the heart.

electrochemical gradient

The concentration gradient of an ion across a membrane plus the voltage difference across that membrane.

electroencephalogram (EEG)

A graphic recording of electrical potentials from the brain.

electromagnetic radiation

A self-propagating wave that travels through space and has both electrical and magnetic properties.

electron

A subatomic particle outside the nucleus carrying a negative charge and very little mass.

electron shell

The region surrounding the atomic nucleus at a fixed energy level in which electrons orbit.

electronegativity

The tendency of an atom to attract electrons when it occurs as part of a compound.

element

A substance that cannot be converted to a simpler substance by ordinary chemical means.

elicitors

Molecules associated with plant pathogens that attach to specialized receptors in plants to initiate a defensive response.

elongation

(1) In molecular biology, the addition of monomers to make a longer RNA or protein during transcription or translation. (2) Growth of a plant axis or cell primarily in the longitudinal direction.

embolus

(em' buh lus) [Gk. *embolos*: stopper] A circulating blood clot. Blockage of a blood vessel by an embolus or a bubble of gas is called an **embolism**. (Contrast with thrombus.)

embryo

[Gk. *en*: within + *bryein*: to grow] A young animal, or young plant sporophyte, while it is still contained within a protective structure such as an egg, uterus, or seed.

embryo sac

In angiosperms, the female gametophyte. Found within the ovule, it consists of

eight or fewer cells, membrane bounded, but without cellulose walls between them.

embryonic stem cell (ESC)

A pluripotent cell in the blastocyst.

emigration

Dispersal of individuals out of an existing population. (Contrast with immigration.)

enamel

The hard material, composed primarily of calcium phosphate, that covers the tooth.

endemic

(en dem' ik) [Gk. *endemos*: native] A species that occurs in a particular location and nowhere else on Earth.

endergonic

A chemical reaction in which the products have higher free energy than the reactants, thereby requiring free energy input to occur. (Contrast with exergonic.)

endocrine gland

(en' doh krin) [Gk. *endo*: within + *krinein*: to separate] An aggregation of secretory cells that secretes hormones into the blood. The endocrine system consists of all endocrine cells and endocrine glands in the body that produce and release hormones. (Contrast with exocrine gland.)

endocrines

Chemical signals released by cells that enter the blood and affect cells anywhere in the body that have appropriate receptors. Also known as hormones.

endocytosis

A process by which liquids or solid particles are taken up by a cell through invagination of the plasma membrane. (Contrast with exocytosis.)

endoderm

[Gk. *endo*: within + *derma*: skin] The innermost of the three embryonic germ layers delineated during gastrulation. Gives rise to the digestive and respiratory tracts and structures associated with them.

endodermis

In plants, a specialized cell layer marking the inside of the cortex in roots and some stems. Frequently a barrier to free diffusion of solutes.

endogenous retroviruses

Retroviruses that have been incorporated into the host's genome.

endomembrane system

A system of intracellular membranes that exchange material with one another, consisting of the Golgi apparatus, endoplasmic reticulum, and lysosomes when present.

endometrium

The epithelial lining of the uterus.

endoparasite

A parasite that lives inside the body of its host organism. (Compare with ectoparasite.)

endophytic fungi

Fungi that live within the aboveground portions of plants without causing obvious harm to the host plant.

endoplasmic reticulum (ER)

[Gk. *endo*: within + L. *reticulum*: net] A system of membranous tubes and flattened sacs found in the cytoplasm of eukaryotes. Exists in two forms: rough ER, studded with ribosomes; and smooth ER, lacking ribosomes.

endorphins

Molecules in the mammalian brain that act as neurotransmitters in pathways that control pain.

endoskeleton

[Gk. *endo*: within + *skleros*: hard] An internal skeleton covered by other, soft body tissues. (Contrast with exoskeleton.)

endosperm

[Gk. *endo*: within + *sperma*: seed] A specialized triploid seed tissue found only in angiosperms; contains stored nutrients for the developing embryo.

endospore

[Gk. *endo*: within + *spora*: to sow] In some bacteria, a resting structure that can survive harsh environmental conditions.

endosymbiosis theory

[Gk. *endo*: within + *sym*: together + *bios*: life] The theory that the eukaryotic cell evolved via the engulfing of one prokaryotic cell by another.

endotherm

[Gk. *endo*: within + *thermos*: heat] An animal that can control its body temperature by the expenditure of its own metabolic energy. (Contrast with ectotherm.)

endotoxin

A lipopolysaccharide that forms part of the outer membrane of certain Gram-negative bacteria that is released when the bacteria grow or lyse. (Contrast with exotoxin.)

energetic cost

The difference between the energy an animal expends in performing a behavior and the energy it would have expended had it rested. (Compare with opportunity cost, risk cost.)

energy budget

A quantitative description of all paths of energy exchange between an animal and its environment.

energy

The capacity to do work or move matter against an opposing force. The capacity to accomplish change in physical and chemical systems.

enhancers

Regulatory DNA sequences that bind transcription factors that either activate or increase the rate of transcription.

enkephalins

Molecules in the mammalian brain that act as neurotransmitters in pathways that control pain.

enteric nervous system

The nerve nets in the submucosa and between the smooth muscle layers of the vertebrate gut.

enthalpy (H)

The total energy of a system.

entrain

To advance or delay an organism's circadian clock each day so that it is in phase with the light-dark cycle of the organism's environment.

entropy (S)

(en' tro pee) [Gk. *tropein*: to change] A measure of the degree of disorder in any system. Spontaneous reactions in a closed system are always accompanied by an increase in entropy.

enveloped virus

A virus enclosed within a phospholipid membrane derived from its host cell.

environmental genomics

Sequencing technique used when biologists are unable to work with the whole genome of a prokaryote species but instead examine individual genes collected from a random sample of the organism's environment.

environmentalism

The use of ecological knowledge, along with economics, ethics, and many other considerations, to inform both personal decisions and public policy relating to stewardship of natural resources and ecosystems.

enzyme-substrate complex (ES)

An intermediate in an enzyme-catalyzed reaction; consists of the enzyme bound to its substrate(s).

epiblast

The upper or overlying portion of the avian blastula which is joined to the hypoblast at the margins of the blastodisc.

epiboly

The movement of cells over the surface of the blastula toward the forming blastopore.

epidermis

[Gk. *epi*: over + *derma*: skin] In plants and animals, the outermost cell layers. (Only one cell layer thick in plants.)

epididymis

(epuh did' uh mus) [Gk. *epi*: over + *didymos*: testicle] Coiled tubules in the testes that store sperm and conduct sperm from the seminiferous tubules to the vas deferens.

epigenetics

The scientific study of changes in the expression of a gene or set of genes that occur without change in the DNA sequence.

epiglottis

The flap of tissue that covers the entrance of the larynx to prevent food and liquid from entering the trachea.

epinephrine

(ep i nef' rin) [Gk. *epi*: over + *nephros*: kidney] The "fight or flight" hormone produced by the medulla of the adrenal gland; it also functions as a neurotransmitter. Also known as adrenaline.

epiphyseal plates

Plates of cartilage near the ends of long bones where bone growth occurs up to adolescence when growth ceases.

epistasis

Interaction between genes in which the presence of a particular allele of one gene determines whether another gene will be expressed.

epithelial tissue

A type of animal tissue made up of sheets of cells that lines or covers organs, makes up tubules, and covers the surface of the body; one of the four major tissue types in multicellular animals.

epitope

See antigenic determinant.

epoch

A subdivision of a period in a geological time scale.

equilibrium

Any state of balanced opposing forces and no net change.

ER

See endoplasmic reticulum.

erection

The state of the penis in which it is stiffened by engorgement with blood.

error signal

In regulatory systems, any difference between the set point of the system and its current condition.

ERV

See expiratory reserve volume.

erythrocyte

(ur rith' row site) [Gk. *erythros*: red + *kytos*: container] A red blood cell.

erythropoietin (EPO)

(ur rith' row poi' i tn) A hormone produced by the kidney in response to lack of oxygen that stimulates the production of red blood cells.

ESC

See embryonic stem cell.

esophagus

(i soff' i gus) [Gk. *oisophagos*: gullet] That part of the gut between the pharynx and the stomach.

essential amino acids

Amino acids that an animal cannot synthesize for itself and must obtain from its food.

essential element

A mineral nutrient required for normal growth and reproduction in plants and animals.

essential fatty acids

Fatty acids that an animal cannot synthesize for itself and must obtain from its food.

ester linkage

A condensation (water-releasing) reaction in which the carboxyl group of a fatty acid reacts with the hydroxyl group of an alcohol. Lipids, including most membrane lipids, are formed in this way. (Contrast with ether linkage.)

estivation

(ess tuh vay' shun) [L. *aestivalis*: summer] A state of dormancy and hypometabolism that occurs during the summer; usually a means of surviving

drought and/or intense heat. (Contrast with hibernation.)

estrogen

Any of several steroid sex hormones; produced chiefly by the ovaries in mammals.

estrus

(es' trus) [L. *oestrus*: frenzy] The period of heat, or maximum sexual receptivity, in some female mammals. Ordinarily, estrus is also the time of release of eggs in the female.

estuary

An aquatic habitat in which salt water and fresh water mix, as when a river meets the ocean. Includes such ecosystems as salt marshes, mangrove forests, mudflats, and seagrass beds.

ether linkage

The linkage of two hydrocarbons by an oxygen atom (HC—O—CH). Ether linkages are characteristic of the membrane lipids of the Archaea. (Contrast with ester linkage.)

ethology

[Gk. *ethos*: character + *logos*: study] An approach to the study of animal behavior that focuses on studying many species in natural environments and addresses questions about the evolution of behavior. (Compare with behaviorism.)

ethylene

One of the plant growth hormones, the gas $\text{H}_2\text{C}=\text{CH}_2$. Involved in fruit ripening and other growth and developmental responses.

etiolated

Process in flowering plants grown in the absence of light; characterized by long weak stems, smaller leaves due to longer internodes, and a pale yellow color.

euchromatin

Diffuse, uncondensed chromatin. Contains active genes that will be transcribed into mRNA. (Contrast with heterochromatin.)

eudicots

Angiosperms with two embryonic cotyledons. (See *also* monocots.)

eukaryotes

(yew car' ree oats) [Gk. *eu*: true + *karyon*: kernel or nucleus] Organisms whose cells contain their genetic material inside a nucleus. Includes all life other than the viruses, prokaryotic archaea, and bacteria. (Contrast with prokaryotes.)

eusocial

Pertaining to a social group that includes nonreproductive individuals, as in honey bees.

eustachian tube

A connection between the middle ear and the throat that allows air pressure to equilibrate between the middle ear and the outside world. Also called the pharyngotympanic tube.

eutrophication

(yoo trofe' ik ay' shun) [Gk. *eu*: truly + *trephein*: to flourish] A process in aquatic ecosystems initiated by a pulse of nutrients that results in an increase of algal growth that may lead to decomposition and depleted oxygen conditions (hypoxia).

evaporation

The transition of water from the liquid to the gaseous phase.

evapotranspiration

The evaporative transfer of heat and water from the surfaces of plants into the atmosphere, which reduces air temperature and increases moisture.

evolution

Any gradual change. Most often refers to organic or Darwinian evolution, which is the genetic and resulting phenotypic change in populations of organisms from generation to generation. (See macroevolution, microevolution. Contrast with speciation.)

evolutionary developmental biology (evo-devo)

The study of the interplay between evolutionary and developmental processes, with a focus on the genetic changes that give rise to novel morphology. Key concepts of evo-devo include modularity, genetic toolkits, genetic switches, and heterochrony.

evolutionary radiation

The proliferation of many species within a single evolutionary lineage.

evolutionary reversal

The reappearance of an ancestral trait in a group that had previously acquired a derived trait.

evolutionary theory

The understanding and application of the mechanisms of evolutionary change to biological problems.

ex vivo gene therapy

Alteration of the human genome sequence in the cells removed from the body and then reimplanted into the body for medical benefit.

excision repair

DNA repair mechanism that removes damaged DNA and replaces it with the appropriate nucleotide.

excretory systems

In animals, organs that maintain the volume, solute concentration, and composition

of the extracellular fluid by excreting water, solutes, and nitrogenous wastes in the form of urine.

executive functions

Cognitive processes (e.g., attentional control, inhibitory control, reasoning, problem solving, planning) that allow goal-directed control of thought and behavior.

exergonic

A chemical reaction in which the products of the reaction have lower free energy than the reactants, resulting in a release of free energy. (Contrast with endergonic.)

exocrine gland

(eks' oh krin) [Gk. *exo*: outside + *krinein*: to separate] Any gland, such as a salivary gland, that secretes to the outside of the body or into the gut. (Contrast with endocrine gland.)

exocytosis

A process by which a vesicle within a cell fuses with the plasma membrane and releases its contents to the outside. (Contrast with endocytosis.)

exon

A portion of a DNA molecule, in eukaryotes, that codes for part of a polypeptide. (Contrast with intron.)

exoskeleton

(eks' oh skel' e ton) [Gk. *exos*: outside + *skleros*: hard] A hard covering on the outside of the body to which muscles are attached. (Contrast with endoskeleton.)

exotoxin

A highly toxic, usually soluble protein released by living, multiplying bacteria. (Contrast with endotoxin.)

expanding triplet repeat

A three-base-pair sequence in a human gene that is unstable and can be repeated a few to hundreds of times. Often, the more the repeats, the less the activity of the gene involved. Expanding triplet repeats occur in some human diseases such as Huntington's disease and fragile-X syndrome.

expiratory reserve volume (ERV)

The amount of air that can be forcefully exhaled beyond the normal tidal expiration. (Contrast with inspiratory reserve volume, tidal volume, vital capacity.)

exploitation competition

Competition in which both species reduce the quantities of their shared but limited resources. (Contrast with interference competition.)

exponential growth

A pattern of population growth characterized by a multiplicative pattern in which, as the number of individuals increases, the number of new individuals added per unit

time accelerates. (Contrast with logistic growth.)

expression vector

A DNA vector, such as a plasmid, that carries a DNA sequence for the expression of an inserted gene into mRNA and protein in a host cell.

expressivity

The degree to which a genotype is expressed in the phenotype; may be affected by the environment.

extensor

A muscle that extends an appendage. (Contrast with flexor.)

external fertilization

The release of gametes into the environment; typical of aquatic animals. Also called spawning. (Contrast with internal fertilization.)

external gills

Highly branched and folded extensions of the body surface that provide a large surface area for gas exchange with water; typical of larval amphibians and many larval insects.

extracellular fluid

In closed circulatory systems refers to the fluid in the circulatory system and the fluid outside it.

extracellular matrix

A material of heterogeneous composition surrounding cells and performing many functions including adhesion of cells.

extraembryonic membranes

Four membranes that support but are not part of the developing embryos of reptiles, birds, and mammals, defining these groups phylogenetically as amniotes. (See amnion, allantois, chorion, yolk sac.)

extreme halophiles

A group of euryarchaeotes that live exclusively in very salty environments.

extremophiles

Archaea and bacteria that live and thrive under conditions (e.g., extremely high temperatures) that would kill most organisms.

eye cups

Photosensory organs in flatworms; components of one of the simplest visual systems in animals.

F

F₁

The first filial generation; the immediate progeny of a parental (P) mating.

F₂

The second filial generation; the immediate progeny of a mating between members of the F₁ generation.

facilitated diffusion

Passive movement through a membrane involving a specific carrier protein; does not proceed against a concentration gradient. (Contrast with active transport, diffusion.)

facilitation

A positive interaction. See positive interaction.

facultative

A type of species interaction that is optional to at least one species involved in the interaction. (Compare with obligate.)

facultative anaerobe

A prokaryote that can shift its metabolism between anaerobic and aerobic modes depending on the presence or absence of O₂. Alternatively, facultative aerobe. (Compare with obligate anaerobe.)

facultative parasite

An organism that can parasitize other living organisms but is also capable of growing independently.

fast-twitch fibers

Skeletal muscle fibers that can generate high tension rapidly, but fatigue rapidly ("sprinter" fibers). Characterized by an abundance of enzymes of glycolysis. (Compare to slow-twitch fibers.)

fat

(1) A triglyceride that is solid at room temperature. (Contrast with oil.) (2) Adipose tissue, one type of connective tissue. (See brown fat.)

fate map

A diagram of the blastula showing which cells (blastomeres) are "fated" to contribute to specific tissues and organs in the mature body.

fatty acid

A molecule made up of a long nonpolar hydrocarbon chain and a polar carboxyl group. Found in many lipids.

fauna

(faw' nah) All the animals found in a given area. (Contrast with flora.)

FD (FLOWERING LOCUS D)

Gene coding for a transcription factor in the shoot apical meristem that binds to florigen; involved in the induction of flowering.

feather

A structure growing from the skin of theropods (living birds and their extinct relatives) that consists of a hollow shaft fringed with vanes of barbs. Functions to support flight, plumage display, and thermoregulation.

feces

[L. *faeces*: dregs] Waste excreted from the digestive system.

fecundity (m_x)

The average number of offspring produced by each individual (or female) within the population.

feedback

In regulatory systems, information about the relationship between the set point of the system and its current state. (Contrast with feedforward information.)

feedforward information

In regulatory systems, information that changes the set point of the system. (Contrast with feedback.)

fenestrations

Small holes in the walls of some capillaries.

fermentation

(fur men tay' shun) [L. *fermentum*: yeast] The anaerobic degradation of a substance such as glucose to smaller molecules such as lactic acid or alcohol with the extraction of energy.

fertilization

Union of gametes. Also known as syngamy.

fertilizer

Any of a number of substances added to soil to improve the soil's capacity to support plant growth. May be organic or inorganic.

fiber

In angiosperms, an elongated, tapering sclerenchyma cell, usually with a thick cell wall, that serves a support function in xylem. (See *also* muscle fiber.)

fibrin

A protein that polymerizes to form long threads that provide structure to a blood clot.

fibrinogen

A circulating protein that can be stimulated to fall out of solution and provide the structure for a blood clot.

fibrous root system

A root system typical of monocots composed of numerous thin adventitious roots

that are all roughly equal in diameter. (Contrast with taproot system.)

Fick's law of diffusion

An equation that describes the factors that determine the rate of diffusion of a molecule from an area of higher concentration to an area of lower concentration.

fight-or-flight response

A rapid physiological response to a sudden threat mediated by the hormone epinephrine.

filament

In flowers, the part of a stamen that supports the anther.

filter feeder

An organism that feeds on organisms much smaller than itself that are suspended in water or air by means of a straining device. Also called suspension feeder.

first filial generation

See F_1 .

first law of thermodynamics

The principle that energy can be neither created nor destroyed.

first polar body

The small daughter cell from the first meiotic division of a primary oocyte.

fitness

The contribution of a genotype or phenotype to the genetic composition of subsequent generations, relative to the contribution of other genotypes or phenotypes. (See *also* inclusive fitness.)

fixed action pattern

In ethology, a genetically determined behavior that is performed without learning, stereotypic (performed the same way each time), and not modifiable by learning.

fixed

In population genetics, the change in a gene pool where there are at least two alleles of a gene to a situation where only one allele remains.

flagellum

(fla jell' um) (plural: flagella) [L. *flagellum*: whip] Long, whiplike appendage that propels cells. Prokaryotic flagella differ sharply from those found in eukaryotes.

flexor

A muscle that flexes an appendage. (Contrast with extensor.)

flora

(flore' ah) All of the plants found in a given area. (Contrast with fauna.)

floral meristem

In angiosperms, a meristem that forms the floral organs (sepals, petals, stamens, and carpels).

floral organ identity genes

In angiosperms, genes that determine the fates of floral meristem cells; their expression is triggered by the products of meristem identity genes.

florigen

A plant hormone involved in the conversion of a vegetative shoot apex to a flower.

flower

The sexual structure of an angiosperm.

fluid feeder

An animal that feeds on fluids it extracts from the bodies of other organisms; examples include nectar-feeding birds and bloodsucking insects.

fluid mosaic model

A molecular model for the structure of biological membranes consisting of a fluid phospholipid bilayer in which suspended proteins are free to move in the plane of the bilayer.

foliose

Having a leafy growth form.

follicle

[L. *folliculus*: little bag] In female mammals, an immature egg surrounded by nutritive cells.

follicle-stimulating hormone (FSH)

A gonadotropin produced by the anterior pituitary.

food web

A representation of the trophic or energetic connections among species within a community.

forebrain

The region of the vertebrate brain that comprises the cerebrum, thalamus, and hypothalamus. (Compare with hindbrain, midbrain.)

fossil fuels

Fuels, including oil, natural gas, coal, and peat, formed over geologic time from organic material buried in anaerobic sediments.

foundation species

A species that has large, community-wide effects as a consequence of its large size and abundance, and its provision of habitat or food for other species.

founder effect

Random changes in allele frequencies resulting from establishment of a population by a very small number of individuals.

fovea

[L. *fovea*: a small pit] In the vertebrate retina, the area of most distinct vision.

frame-shift mutation

The addition or deletion of a single or two adjacent nucleotides in a gene's sequence. Results in the misreading of mRNA during translation and the production of a nonfunctional protein. (Contrast with missense mutation, nonsense mutation, silent mutation.)

Frank–Starling law

The principle that the stroke volume of the heart increases with increased return of blood to the heart.

free energy (G)

Energy that is available for doing useful work, after allowance has been made for the increase or decrease of disorder.

free-running

A descriptor of an endogenous rhythm that is not entrained by an environmental cue.

frequency distribution

A figure that displays the frequency of different classes of data.

frequency-dependent selection

Selection that changes in intensity with the proportion of individuals in a population having the trait.

frontal lobe

The largest of the brain lobes in humans; involved with feeling and planning functions; includes the primary motor cortex.

frugivore

[L. *frugis*: fruit + *vorare*: to devour] An animal that eats fruit.

fruit

In angiosperms, a ripened and mature ovary (or group of ovaries) containing the seeds. Sometimes applied to reproductive structures of other groups of plants.

fruticose

Having a shrubby growth form.

FSH

See follicle-stimulating hormone.

FT (FLOWERING LOCUS T)

Gene that codes for florigen, a small, diffusible protein involved in the induction of

flowering.

fugitive species

A species that leave an otherwise suitable habitat in order to avoid competition with another species.

full census

A count of every individual in a population.

functional genomics

The assignment of functional roles to the proteins encoded by genes identified by sequencing entire genomes.

functional group

(1) A characteristic combination of atoms that contributes specific properties (such as charge or polarity) when attached to larger molecules (e.g., carboxyl group, amino group). (2) A group of species that function in similar ways, whether or not they use the same resources. (Compare with guild.)

functional residual volume (FRV)

The residual volume plus the expiratory reserve volume.

fundamental niche

A species' niche as defined by its physiological capabilities. (Contrast with realized niche.)

G**G protein**

A membrane protein involved in signal transduction; characterized by binding GDP or GTP.

G protein–coupled receptors

A class of receptors that change configuration upon ligand binding such that a G protein binding site is exposed on the cytoplasmic domain of the receptor, initiating a signal transduction pathway.

G0

A resting phase in which a cell is not preparing for the cell division cycle.

G1

In the cell cycle, the gap between the end of mitosis and the onset of the S phase.

G1-to-S transition

In the cell cycle, the point at which G1 ends and the S phase begins.

G2

In the cell cycle, the gap between the S (synthesis) phase and the onset of mitosis.

gain-of-function mutation

A mutation that results in a protein with a new function. (Contrast with loss-of-function mutation.)

gallbladder

In the human digestive system, an organ in which bile is stored.

gametangium

(gam uh tan' gee um) (plural: gametangia) [Gk. *gamos*: marriage + *angeion*: vessel] Any plant or fungal structure within which a gamete is formed.

gamete

(gam' eet) [Gk. *gamete/gametes*: wife, husband] The mature sexual reproductive cell: the egg or the sperm.

gametogenesis

(ga meet' oh jen' e sis) The specialized series of cellular divisions that leads to the production of gametes. Called oogenesis when referring to processes in the ovary and spermatogenesis in the testis.

gametophyte

(ga meet' oh fyte) In plants and photosynthetic protists with alternation of generations, the multicellular haploid phase that produces the gametes. (Contrast with sporophyte.)

gamma diversity

Species diversity within a geographic region; the regional species pool. (Compare with alpha diversity, beta diversity.)

ganglion

(gang' glee un) (plural: ganglia) [Gk. lump] A cluster of neurons that have similar characteristics or function.

ganglion cells

Cells at the front of the human retina that transmit information from the bipolar cells to the brain.

gap genes

In *Drosophila* development, segmentation genes that define broad areas along the anterior–posterior axis of the early embryo. Part of a developmental cascade that includes maternal effect genes, pair rule genes, segment polarity genes, and Hox genes.

gap junction

A 2.7-nanometer gap between cell membranes of two animal cells, spanned by protein channels. Gap junctions allow chemical substances or electrical signals to pass from cell to cell.

gastric pits

Deep infoldings in the walls of the stomach lined with secretory cells.

gastrin

A hormone secreted by cells in the lower region of the stomach that stimulates the secretion of digestive juices as well as movements of the stomach.

gastrointestinal system

See gut.

gastrovascular cavity

Serving for both digestion (gastro) and circulation (vascular); in particular, the central cavity of the body of jellyfish and other cnidarians.

gastrovascular system

A branching body cavity in Cnidaria and Platyhelminthes that has one opening to the environment and serves to digest food and distribute nutrients to the body.

gastrulation

Development of a blastula into a gastrula. In embryonic development, the process by which a blastula is transformed by massive movements of cells into a gastrula, an embryo with three germ layers and distinct body axes.

gated channel

A membrane protein that changes its three-dimensional shape, and therefore its ion conductance, in response to a stimulus. When open, it allows specific ions to move across the membrane.

gel electrophoresis

(e lek' tro fo ree' sis) [L. *electrum*: amber + Gk. *phorein*: to bear] A technique for separating molecules (such as DNA fragments) from one another on the basis of their electric charges and molecular weights by applying an electric field to a gel.

gene

[Gk. *genes*: to produce] A unit of heredity. Used here as the unit of genetic function which carries the information for a polypeptide or RNA.

gene duplication

The generation of extra copies of a gene in a genome over evolutionary time. A mechanism by which genomes can acquire new functions.

gene expression

The transcription and translation into a protein of the information (nucleotide sequence) contained in a gene.

gene family

A set of similar genes derived from a single parent gene; need not be on the same chromosomes. The vertebrate globin genes constitute a classic example of a gene family.

gene pool

All of the different alleles of all of the genes existing in all individuals of a

population.

gene therapy

Treatment of a genetic disease by providing patients with cells containing functioning alleles of the genes that are nonfunctional in their bodies.

gene tree

A graphic representation of the evolutionary relationships of a single gene in different species or of the members of a gene family.

gene-for-gene concept

In plants, a mechanism of resistance to pathogens in which resistance is triggered by the specific interaction of the products of a pathogen's *Avr* genes and a plant's *R* genes.

general transcription factors

In eukaryotes, transcription factors that bind to the promoters of most protein-coding genes and are required for their expression. Distinct from transcription factors that have specific regulatory effects only at certain promoters or classes of promoters.

generation time (G)

The average age of the parents of all the offspring produced within a cohort.

genetic code

The set of instructions, in the form of nucleotide triplets, that translate a linear sequence of nucleotides in mRNA into a linear sequence of amino acids in a protein.

genetic drift

Changes in gene frequencies from generation to generation as a result of random (chance) processes.

genetic marker

(1) In gene cloning, a gene of identifiable phenotype that indicates the presence of another gene, DNA segment, or chromosome fragment. (2) In general, a DNA sequence such as a single nucleotide polymorphism whose presence is correlated with the presence of other linked genes on that chromosome.

genetic screen

A technique for identifying genes involved in a biological process of interest. Involves creating a large collection of randomly mutated organisms and identifying those individuals that are likely to have a defect in the pathway of interest. The mutated gene(s) in those individuals can then be isolated for further study.

genetic structure

The frequencies of different alleles at each locus and the frequencies of different genotypes in a Mendelian population.

genetic switches

Mechanisms that control how the genetic toolkit is used, such as promoters and the transcription factors that bind them. The signal cascades that converge on and operate these switches determine when and where genes will be turned on and off.

genetic toolkit

A set of developmental genes and proteins that is common to most animals and is hypothesized to be responsible for the evolution of their differing developmental pathways.

genetics

The scientific study of the structure, functioning, and inheritance of genes, the units of hereditary information.

genitalia

The reproductive organs, especially the external accessory sex organs.

genome

(jee' nome) The complete DNA sequence for a particular organism or individual.

genome sequencing

Determination of the nucleotide base sequence of the entire genome of an organism.

genomic equivalence

All somatic cells in a complex organism have the entire genome of that organism.

genomic library

All of the cloned DNA fragments generated by the breakdown of genomic DNA into smaller segments.

genomics

The scientific study of entire sets of genes and their interactions.

genotype

(jean' oh type) [Gk. *gen*: to produce + *typos*: impression] An exact description of the genetic constitution of an individual, either with respect to a single trait or with respect to a larger set of traits. (Contrast with phenotype.)

genus

(jean' us) (plural: genera) [Gk. *genos*: stock, kind] A group of related, similar species recognized by taxonomists with a distinct name used in binomial nomenclature.

geographic range

The entire region within which a species occurs.

geological time scale

The division of Earth's history into ordered, named periods of time, based on major

biotic and abiotic changes.

germ cell

[L. *germen*: to beget] A reproductive cell or gamete of a multicellular organism. (Contrast with somatic cell.)

germ layers

The three embryonic layers formed during gastrulation (ectoderm, mesoderm, and endoderm). Also called cell layers or tissue layers.

germ line gene therapy

Alteration of the human genome sequence in the gametes or cells giving rise to gametes for medical benefit. (Contrast with somatic cell gene therapy.)

germ line mutation

Mutation in a cell that produces gametes (i.e., a germ line cell). (Contrast with somatic mutation.)

germination

Sprouting of a seed or spore.

gestation

(jes tay' shun) [L. *gestare*: to bear] The period during which the embryo of a mammal develops within the uterus. Also known as pregnancy.

GH

See growth hormone.

GHIH

See growth hormone inhibiting hormone.

ghrelin

A hormone produced and secreted by cells in the stomach that stimulates appetite.

gibberellin

(jib er el' lin) A class of plant growth hormones playing roles in stem elongation, seed germination, flowering of certain plants, etc.

gizzard

(giz' erd) [L. *gigeria*: cooked chicken parts] The second of two stomachlike organs in birds, other reptiles, earthworms, and various insects, that grinds up food, sometimes with the aid of fragments of stone. (See *also* crop.)

glans penis

The highly sensitive tip of the mammalian penis.

glia

(glee' uh) [Gk. *glia*: glue] One of the two classes of neural cells (along with neurons, with which glia interact); glia do not typically conduct action potentials. Types of glia include astrocytes, oligodendrocytes, and Schwann cells.

glomerular filtration rate (GFR)

The rate at which the blood is filtered in the glomeruli of the kidney.

glomerulus

(glo mare' yew lus) (plural: glomeruli) [L. *glomus*: ball] Sites in the kidney where blood filtration takes place. Each glomerulus consists of a knot of capillaries served by afferent and efferent arterioles.

glucagon

Hormone produced by alpha cells of the pancreatic islets of Langerhans. Glucagon stimulates the liver to break down glycogen and release glucose into the circulation.

gluconeogenesis

The biochemical synthesis of glucose from other substances, such as amino acids, lactate, and glycerol.

glucose

[Gk. *gleukos*: sugar, sweet wine] The most common monosaccharide; the monomer of the polysaccharides starch, glycogen, and cellulose.

glyceraldehyde 3-phosphate (G3P)

A phosphorylated three-carbon sugar; an intermediate in glycolysis and photosynthetic carbon fixation.

glycerol

(gliss' er ole) A three-carbon alcohol with three hydroxyl groups; a component of phospholipids and triglycerides.

glycogen

(gly' ko jen) [Gk. *glyk*: sweet] An energy storage polysaccharide found in animals and fungi; a branched-chain polymer of glucose, similar to starch.

glycolipid

A lipid to which sugars are attached.

glycolysis

(gly kol' li sis) [Gk. *gleukos*: sugar + *lysis*: break apart] The enzymatic breakdown of glucose to pyruvic acid.

glycoprotein

A protein to which sugars are attached.

glycosidic linkage

Bond between carbohydrate (sugar) molecules through an intervening oxygen atom (–O–).

glycosylation

The addition of carbohydrates to another type of molecule, such as a protein.

glyoxysome

(gly ox' ee soam) An organelle found in plants, in which stored lipids are converted to carbohydrates.

goiter

Swelling in the neck resulting from an enlarged thyroid gland.

Goldman equation

An equation that calculates membrane potential by taking into consideration the concentration differences of all ions on both sides of the membrane and the relative permeability of the membrane to those ions.

Golgi apparatus

(goal' jee) A system of concentrically folded membranes found in the cytoplasm of eukaryotic cells; functions in secretion from the cell by exocytosis.

Golgi tendon organ

A mechanoreceptor found in tendons and ligaments; provides information about the force generated by a contracting muscle.

gonad

(go' nad) [Gk. *gone*: seed] An organ that produces gametes in animals: either an ovary (female gonad) or testis (male gonad).

gonadotropin

A trophic hormone that stimulates the gonads.

gonadotropin-releasing hormone (GnRH)

Hormone produced by the hypothalamus that stimulates the anterior pituitary to secrete gonadotropins.

Gondwana

The large southern land mass that existed from the Cambrian (540 mya) to the Jurassic (138 mya). Present-day remnants are South America, Africa, India, Australia, and Antarctica.

graded membrane potential

Small local change in membrane potential caused by opening or closing of ion channels.

grafting

Artificial transplantation of tissue from one organism to another. In horticulture, the transfer of a bud or stem segment from one plant onto the root of another as a form of asexual reproduction.

Gram-negative bacteria

Bacteria that appear red when stained using the Gram-staining technique. These bacteria have an outer membrane outside the relatively thin peptidoglycan layer of

the cell wall.

Gram-positive bacteria

Bacteria that appear blue to purple when stained using the Gram-staining technique. These bacteria have an outer cell wall consisting of a thick layer of peptidoglycan.

Gram stain

A differential purple stain useful in characterizing bacteria. The peptidoglycan-rich cell walls of gram-positive bacteria stain purple; cell walls of gram-negative bacteria generally stain orange.

granulosa cells

Cells of the ovarian follicle of mammals that surround and nurture the oocyte.

gravitropism

[L. *gravitas*: weight, force + Gk. *tropos*: to turn] A directed plant growth response to gravity.

gray crescent

In frog development, a band of diffusely pigmented cytoplasm on the side of the egg opposite the site of sperm entry. Arises as a result of cytoplasmic rearrangements that establish the anterior–posterior axis of the zygote.

gray matter

In the nervous system, tissue that is rich in neuronal cell bodies. (Contrast with white matter.)

greenhouse gases

Gases in the atmosphere, such as carbon dioxide and methane, that are transparent to sunlight, but trap heat radiating from Earth's surface, causing heat to build up at Earth's surface.

gross primary production (GPP)

The total amount of carbon fixed by primary producers in an ecosystem. (Compare with net primary production.)

ground meristem

That part of an apical meristem that gives rise to the ground tissue system of the primary plant body.

ground tissue system

Those parts of the plant body not included in the dermal or vascular tissue systems. Ground tissues function in storage, photosynthesis, and support.

growth

An increase in the size of the body and its organs by cell division and cell expansion.

growth factor

A chemical signal that stimulates cells to divide.

growth hormone (GH)

A peptide hormone released by the anterior pituitary that stimulates many anabolic processes.

growth hormone inhibiting hormone (GHIH)

Also called somatostatin, a peptide hormone produced in the hypothalamus that inhibits the activity of growth hormone secreting cells in the anterior pituitary.

guanine (G)

(gwan' een) A nitrogen-containing base found in DNA, RNA, and GTP.

guard cells

In plants, specialized, paired epidermal cells that surround and control the opening of a stoma (pore).

guild

A group of species, often taxonomically distinct, that use the same resources. (Compare with functional group.)

gustation

The sense of taste.

gut

An animal's digestive tract.

gymnosperms

Seed plants that do not produce flowers or fruits; one of the two major groups of living seed plants. (See *also* angiosperms.)

gyres

Large-scale circular ocean currents caused by prevailing winds and Earth's rotation.

gyri

(singular: gyrus) The ridges (folds) in the cerebral cortex.

H**habitat**

The particular environment in which an organism lives.

habitat degradation

The conversion of an ecosystem by human activities that reduces habitat quality. (Compare with habitat loss.)

habitat loss

The conversion of an ecosystem by human activities that reduces habitat quantity.

(Compare with habitat degradation.)

hair cell

A type of mechanoreceptor in animals. Detects sound waves and other forms of motion in air or water.

half-life

The time required for half of a sample of a radioactive isotope to decay to its stable, nonradioactive form, or for a drug or other substance to reach half its initial dosage.

halophytes

Organisms that can grow in high salinity.

Hamilton's rule

The principle that, for an apparent altruistic behavior to be adaptive, the fitness benefit of that act to the recipient times the degree of relatedness of the performer and the recipient must be greater than the cost to the performer.

haplodiploidy

A sex determination mechanism in which diploid individuals (which develop from fertilized eggs) are female and haploid individuals (which develop from unfertilized eggs) are male; typical of hymenopterans.

haploid

(hap' loid) [Gk. *haploeides*: single] Having a chromosome complement consisting of just one copy of each chromosome; designated $1n$ or n . (Contrast with diploid.)

haplotype

Linked nucleotide sequences that are usually inherited as a unit (as a "sentence" rather than as individual "words").

Hardy-Weinberg equilibrium

In a sexually reproducing population, the allele frequency at a given locus that is not being acted on by agents of evolution; the conditions that would result in no evolution in a population.

haustorium

(haw stor' ee um) (plural: haustoria) [L. *haustus*: draw up] A specialized hypha or other structure by which fungi and some parasitic plants draw nutrients from a host plant.

Haversian systems

Units of organization in compact bone that reflect the action of intercommunicating osteoblasts.

hCG

See human chorionic gonadotropin.

HDLs

See high-density lipoproteins.

heart

In circulatory systems, a muscular pump that moves extracellular fluid around the body.

heat of vaporization

The energy that must be supplied to convert a molecule from a liquid to a gas at its boiling point.

heat shock proteins

Chaperone proteins expressed in cells exposed to high or low temperatures or other forms of environmental stress.

hematocrit

The proportion of the blood volume that consists of red blood cells.

hemiparasite

A parasitic plant that can photosynthesize, but derives water and mineral nutrients from the living body of another plant. (Contrast with holoparasite.)

hemizygous

(hem' ee zie' gus) [Gk. *hemi*: half + *zygotos*: joined] In a diploid organism, having only one allele for a given trait, typically the case for X-linked genes in male mammals and Z-linked genes in female birds. (Contrast with homozygous, heterozygous.)

hemocoel

The primary body cavity of many invertebrates, which contains circulatory fluid.

hemoglobin

(hee' mo glow bin) [Gk. *heaema*: blood + L. *globus*: globe] Oxygen-transporting protein found in the red blood cells of vertebrates (and found in some invertebrates).

hemolymph

The extracellular fluid in closed circulatory systems.

Hensen's node

In avian embryos, a structure at the anterior end of the primitive groove; determines the fates of cells passing over it during gastrulation.

hepatic portal vein

The vein that begins in capillary beds in the gut and ends in capillary beds in the liver.

herbivore

(ur' bi vore) [L. *herba*: plant + *vorare*: to devour] An animal that eats plant tissues. (Contrast with carnivore, detritivore, omnivore.)

herbivory

(ur' bi vore) [L. *herba*: plant + *vorare*: to devour] An act of predation in which the predator is animal and the prey is a plant or algae. (Contrast with carnivory, parasitism, omnivory.)

hermaphroditism

(her maf' row dite ism) The coexistence of both female and male sex organs in the same organism.

heterochromatin

Densely packed, dark-staining chromatin; any genes it contains are usually not transcribed. (Contrast with euchromatin.)

heterochrony

[Gk. different time] Alteration in the timing of developmental events, contributing to the evolution of different phenotypes in the adult. (Contrast with heterometry, heterotypy.)

heterocyst

A large, thick-walled cell type in the filaments of certain cyanobacteria that performs nitrogen fixation.

heterometry

[Gk. different measure] Alteration in the level of gene expression, and thus in the amount of protein produced, during development, contributing to the evolution of different phenotypes in the adult. (Contrast with heterochrony, heterotypy.)

heteromorphic

(het' er oh more' fik) [Gk. different form] Having a different form or appearance, as two heteromorphic life stages of a plant. (Contrast with isomorphic.)

heterosis

The superior fitness of heterozygous offspring as compared with that of their dissimilar homozygous parents. Also called hybrid vigor.

heterosporous

(het' er os' por us) Producing two types of spores, one of which gives rise to a female megaspore and the other to a male microspore. (Contrast with homosporous.)

heterotherm

An animal that regulates its body temperature at a constant level at some times but not others, such as a hibernator.

heterotopy

[Gk. different place] Spatial differences in gene expression during development, controlled by developmental regulatory genes and contributing to the evolution of distinctive adult phenotypes.

heterotroph

(het' er oh trof) [Gk. *heteros*: different + *trophe*: feed] An organism that requires preformed organic molecules as food. (Contrast with autotroph.)

heterotypy

[Gk. different kind] Alteration in a developmental regulatory gene itself rather than the expression of the genes it controls. (Contrast with heterochrony, heterometry.)

heterozygous

(het' er oh zie' gus) [Gk. *heteros*: different + *zygotos*: joined] In diploid organisms, having different alleles of a given gene on the pair of homologs carrying that gene. (Contrast with hemizygous, homozygous.)

hexose

[Gk. *hex*: six] A sugar containing six carbon atoms.

hibernation

[L. *hibernum*: winter] The state of inactivity of some animals during winter; marked by a drop in body temperature and metabolic rate. (Contrast with estivation.)

high-density lipoproteins (HDLs)

Lipoproteins that remove cholesterol from tissues and carry it to the liver; HDLs are the "good" lipoproteins associated with good cardiovascular health.

high-throughput sequencing

Rapid DNA sequencing on a micro scale in which many fragments of DNA are sequenced in parallel.

highly repetitive sequences

Short (less than 100 bp), nontranscribed DNA sequences, repeated thousands of times in tandem arrangements.

hindbrain

The region of the developing vertebrate brain that gives rise to the medulla, pons, and cerebellum. (Compare with forebrain, midbrain.)

hippocampus

[Gk. sea horse] A part of the forebrain that takes part in long-term memory formation.

histamine

(hiss' tah meen) A substance released by damaged tissue, or by mast cells in response to allergens. Histamine increases vascular permeability, leading to edema (swelling).

histogram

A figure that displays frequencies of classes of quantitative data binned by ranges of a particular variable.

HIV

See human immunodeficiency virus.

holometabolous

Undergoing complete metamorphosis.

holoparasite

A fully parasitic plant (i.e., one that does not perform photosynthesis). (Contrast with hemiparasite.)

homeobox

180-base-pair segment of DNA found in certain homeotic genes. A specific sequence within the homeobox—the homeodomain—regulates the expression of other genes and through this regulation controls large-scale developmental processes. (See homeotic genes.)

homeodomain

See homeobox.

homeostasis

(home' ee o sta' sis) [Gk. *homos*: same + *stasis*: position] The maintenance of a steady state, such as a constant temperature, by means of physiological or behavioral feedback responses.

homeotherms

Animals that regulate their body temperatures within a narrow range when confronted with a much greater range of environmental temperatures.

homeotic genes

Genes that act during development to determine the formation of an organ from a region of the embryo. (Compare with Hox genes.)

homeotic mutation

Mutation in a homeotic gene that results in the formation of a different organ than that normally made by a region of the embryo.

homing

In animal navigation, the ability to return to a nest site, burrow, or other specific location.

hominin

Lineages that includes modern humans (*Homo sapiens*) and their extinct ancestors (e.g., Australopithecines, *Homo erectus*).

homolog

(1) In cytogenetics, one of a pair (or larger set) of chromosomes having the same overall genetic composition and sequence. In diploid organisms, each chromosome inherited from one parent is matched by an identical (except for mutational changes) chromosome—its homolog—from the other parent. (2) In evolutionary

biology, one of two or more features in different species that are similar by reason of descent from a common ancestor.

homologous pair

A pair of matching chromosomes made up of a chromosome from each of the two sets of chromosomes in a diploid organism.

homology

(ho mol' o jee) [Gk. *homologia*: of one mind, agreement] A similarity between two or more features that is due to inheritance from a common ancestor. The structures are said to be **homologous**, and each is a **homolog** of the others.

homoplasy

(home' uh play zee) [Gk. *homos*: same + *plastikos*: shape, mold] The presence in multiple groups of a trait that is not inherited from the common ancestor of those groups. Can result from convergent evolution, evolutionary reversal, or parallel evolution.

homosporous

Producing a single type of spore that gives rise to a single type of gametophyte, bearing both female and male reproductive organs. (Contrast with heterosporous.)

homotypic

Pertaining to adhesion of cells of the same type.

homozygous

(home' oh zie' gus) [Gk. *homos*: same + *zygotos*: joined] In diploid organisms, having identical alleles of a given gene on both homologous chromosomes. An individual may be a homozygote with respect to one gene and a heterozygote with respect to another. (Contrast with hemizygous, heterozygous.)

horizons

The horizontal layers of a soil profile, including the topsoil (A horizon), subsoil (B horizon) and parent rock or bedrock (C horizon).

horizontal cells

Cells in the retina that communicate laterally between photoreceptors and bipolar cells.

hormone

(hore' mone) [Gk. *hormon*: to excite, stimulate] A chemical signal produced in minute amounts at one site in a multicellular organism and transported to another site where it acts on target cells.

host

An organism that harbors a parasite or symbiont and provides it with nourishment.

Hox genes

Conserved homeotic genes found in vertebrates, *Drosophila*, and other animal

groups. Hox genes contain the homeobox and specify pattern and axis formation in these animals.

human chorionic gonadotropin (hCG)

A hormone secreted by the placenta that sustains the corpus luteum and helps maintain pregnancy.

Human Genome Project

A publicly and privately funded research effort, successfully completed in 2003, to produce a complete DNA sequence for the entire human genome.

human immunodeficiency virus (HIV)

Human immunodeficiency virus, the retrovirus that causes acquired immune deficiency syndrome (AIDS).

humoral immune response

The response of the immune system mediated by B cells that produces circulating antibodies active against extracellular bacterial and viral infections. (Contrast with cellular immune response.)

humus

(hew' mus) The partly decomposed remains of plants and animals on the surface of a soil.

hybrid vigor

See heterosis.

hybrid zone

A region of overlap in the ranges of two closely related species where the species may hybridize.

hydrocarbon

A compound containing only carbon and hydrogen atoms.

hydrogen bond

A weak electrostatic bond which arises from the attraction between the slight positive charge on a hydrogen atom and a slight negative charge on a nearby oxygen or nitrogen atom.

hydrologic cycle

The movement of water from the oceans to the atmosphere, to the soil, rivers, and lakes, and back to the oceans.

hydrolysis reaction

(high drol' uh sis) [Gk. *hydro*: water + *lysis*: break apart] A chemical reaction that breaks a bond by inserting the components of water ($AB + H_2O \rightarrow AH + BOH$). (Contrast with condensation reaction.)

hydrophilic

(high dro fill' ik) [Gk. *hydro*: water + *philia*: love] Having an affinity for water. (Contrast with hydrophobic.)

hydrophobic

(high dro foe' bik) [Gk. *hydro*: water + *phobia*: fear] Having no affinity for water. Uncharged and nonpolar groups of atoms are hydrophobic. (Contrast with hydrophilic.)

hydrophobic interaction

A weak chemical interaction caused when molecules that are not attracted to water interact to exclude water.

hydroponic

Pertaining to a method of growing plants with their roots suspended in nutrient solutions instead of soil.

hydrostatic skeleton

A fluid-filled body cavity that transfers forces from one part of the body to another when acted on by surrounding muscles.

hyperaccumulators

Plant species that store large quantities of heavy metals such as arsenic, cadmium, nickel, aluminum, and zinc.

hyperpolarization

A change in the resting potential across a membrane so that the inside of a cell becomes more negative compared with the outside of the cell. (Contrast with depolarization.)

hypersensitive response

A defensive response of plants to microbial infection in which phytoalexins and pathogenesis-related proteins are produced and the infected tissue undergoes apoptosis to isolate the pathogen from the rest of the plant.

hypertonic

Having a greater solute concentration. Said of one solution compared with another. (Contrast with hypotonic, isotonic.)

hypertonic regulation

Maintaining body fluids at a greater solute concentration than the environment. (Contrast with hypotonic regulation.)

hypha

(high' fuh) (plural: hyphae) [Gk. *hyphe*: web] In the fungi and oomycetes, any single filament.

hypoblast

The lower tissue portion of the avian blastula which is joined to the epiblast at the margins of the blastodisc.

hypothalamus

The part of the brain lying below the thalamus; it coordinates water balance, reproduction, temperature regulation, and metabolism.

hypothermia

Below-normal body temperature.

hypothesis

A tentative answer to a question, from which testable predictions can be generated. (Contrast with theory.)

hypotonic

Having a lesser solute concentration. Said of one solution in comparing it to another. (Contrast with hypertonic, isotonic.)

hypotonic regulation

Maintaining body fluids at a lesser solute concentration than the environment. (Contrast with hypertonic regulation.)

hypoxia

A deficiency of oxygen.

hysteresis

The inability of a community that has undergone change to shift back to the initial community type, even when the original conditions are restored.

I**igneous rocks**

Rocks solidified from lava or magma.

ileum

The final segment of the small intestine. (See *also* duodenum, jejunum.)

imbibition

Water uptake by a seed; first step in germination.

immediate hypersensitivity

A rapid, extensive overreaction of the immune system against an allergen, resulting in the release of large amounts of histamine. (Contrast with delayed hypersensitivity.)

immediate memory

A form of memory for events happening in the present that is almost perfectly photographic, but lasts only seconds. (Contrast with long-term memory, short-term memory.)

immigration

Dispersal of individuals into an existing population. (Contrast with emigration.)

immunity

[L. *immunis*: exempt from] In animals, the ability to avoid disease when invaded by a pathogen by deploying various defense mechanisms.

immunoglobulins

A class of proteins containing a tetramer consisting of four polypeptide chains—two identical light chains and two identical heavy chains—held together by disulfide bonds; active as receptors and effectors in the immune system.

immunological memory

The capacity to more rapidly and massively respond to a second exposure to an antigen than occurred on first exposure.

imperfect flower

A flower lacking either functional stamens or functional carpels. (Contrast with perfect flower.)

implantation

The process by which the early mammalian embryo becomes attached to and embedded in the lining of the uterus.

imprinting

In animal behavior, a rapid form of learning in which an animal learns, during a brief critical period, to make a particular response (which is then maintained for life) to some object or other organism.

in vitro evolution

A method based on natural molecular evolution that uses artificial selection in the laboratory to rapidly produce molecules with novel enzymatic and binding functions.

in vivo gene therapy

Alteration of the human genome sequence in cells in the body for medical benefit.

inactivation gate

The property of a voltage-gated Na^+ ion channel that decreases its permeability to Na^+ when the membrane is depolarized.

inbreeding

Breeding of two closely genetically related individuals.

inbreeding

depression Reduction of fitness in the offspring of inbreeding.

inclusive fitness

The sum of an individual's genetic contribution to subsequent generations both via production of its own offspring and via its influence on the survival of relatives who are not direct descendants. (See *also* indirect fitness, kin selection. Contrast with direct fitness.)

incomplete cleavage

A pattern of cleavage that occurs in many eggs that have a lot of yolk, in which the cleavage furrows do not penetrate all of it. (See *also* discoidal cleavage, superficial cleavage. Contrast with complete cleavage.)

incomplete dominance

Condition in which the heterozygous phenotype is intermediate between the two homozygous phenotypes.

incomplete metamorphosis

Insect development in which changes between instars are gradual. (Contrast with direct development, complete metamorphosis.)

independent assortment

During meiosis, the random separation of genes carried on nonhomologous chromosomes into gametes so that inheritance of these genes is random. This principle was articulated by Mendel as his second law.

indeterminate growth

An open-ended growth pattern in which an organism or organ continues to grow as long as it lives; characteristic of some animals and of plant shoots and roots. (Contrast with determinate growth.)

indirect fitness

The component of inclusive fitness due to the reproductive success of related individuals times the percentage of shared genes between those individuals (e.g., 50% for a sibling).

indirect interaction

An interaction in which the relationship between two species is mediated by a third (or more) species. (Compare with direct interaction.)

induced

A process that occurs only under certain conditions or signals.

induced fit

A change in the shape of an enzyme caused by binding to its substrate that exposes the active site of the enzyme.

induced mutation

A mutation resulting from exposure to a mutagen from outside the cell. (Contrast with spontaneous mutation.)

induced pluripotent stem cells (iPS cells)

Multipotent or pluripotent animal stem cells produced from differentiated cells *in vitro* by the addition of several genes that are expressed.

inducer

(1) A compound that stimulates the synthesis of a protein. (2) In embryonic

development, a substance that causes a group of target cells to differentiate in a particular way.

inducible

Produced only in the presence of a particular compound or under particular circumstances. (Contrast with constitutive.)

inducible genes

Genes that are expressed only when their products—inducible proteins—are needed.

induction

In embryonic development, the process by which a factor produced and secreted by certain cells determines the fates of other cells.

inductive logic

Involves making observations and then formulating one or more possible scenarios—hypotheses—that might explain those observations. (Contrast with deductive logic.)

inferior vena cava

Large vein that returns deoxygenated blood to the right atrium from the lower body.

inflammation

A nonspecific defense against pathogens; characterized by redness, swelling, pain, and increased temperature.

inflorescence

A structure composed of several to many flowers.

inflorescence meristem

A meristem that produces floral meristems as well as other small leafy structures (bracts).

ingroup

In a phylogenetic study, the group of organisms of primary interest. (Contrast with outgroup.)

initials

Cells that perpetuate plant meristems, comparable to animal stem cells. When an initial divides, one daughter cell develops into another initial, while the other differentiates into a more specialized cell.

initiation

In molecular biology, the beginning of transcription or translation.

initiation complex

In protein translation, a combination of a small ribosomal subunit, an mRNA molecule, and the tRNA charged with the first amino acid coded for by the mRNA;

formed at the onset of translation.

initiation site

The place within a promoter where transcription begins.

innate defenses

In animals, one of two general types of defenses against pathogens. Nonspecific and present in most animals. (Contrast with adaptive defenses.)

inner cell mass

Derived from the mammalian blastula (blastocyst), the inner cell mass that will give rise to the yolk sac (via hypoblast) and embryo (via epiblast).

inorganic fertilizer

A chemical or combination of chemicals applied to soil or plants to make up for a plant nutrient deficiency. Often contains the macronutrients nitrogen, phosphorus, and potassium (N-P-K).

inositol trisphosphate (IP₃)

An intracellular second messenger derived from membrane phospholipids.

inspiratory reserve volume (IRV)

The amount of air that can be inhaled above the normal tidal inspiration. (Contrast with expiratory reserve volume, tidal volume, vital capacity.)

instar

(in' star) An immature stage of an insect between molts.

insular cortex

The outer layers of the insular lobe.

insular lobe

A region of the cerebrum that folds in between the temporal lobes and the overlying frontal and parietal lobes.

insulin

(in' su lin) [L. *insula*: island] A hormone synthesized in islet cells of the pancreas that promotes the conversion of glucose into the storage material, glycogen.

integral membrane proteins

Proteins that are at least partially embedded in the plasma membrane. (Contrast with peripheral membrane proteins.)

integrin

In animals, a transmembrane protein that mediates the attachment of epithelial cells to the extracellular matrix.

integument

[L. *integumentum*: covering] A protective surface structure. In gymnosperms and

angiosperms, a layer of tissue around the ovule that will become the seed coat.

interaction strength

A measure of the effect of one species (the interactor) on the abundance of another species (the target species).

interaction webs

A concept that describes both the trophic (vertical) and non-trophic (horizontal; such as competition, mutualism, commensalism) interactions among the species in a food web.

intercalated discs

Structural features of cardiac muscle cells that connect cells together and provide electrical continuity through gap junctions.

intercostal muscles

Muscles between the ribs that can augment breathing movements by elevating and suppressing the rib cage.

interference competition

Competition in which one species actively interferes with another species' access to a limiting resource. (Contrast with exploitation competition.)

interference RNA (RNAi)

See **RNA** interference.

interferons

Glycoproteins produced by virus-infected animal cells; interferons increase the resistance of neighboring cells to the virus.

intermediate disturbance hypothesis

A hypothesis describing how varying degrees of disturbance (or stress or predation) affects species diversity within communities. Species diversity is greatest at intermediate levels of disturbance because competitive exclusion at low levels of disturbance and mortality at high levels of disturbance reduces species diversity.

intermediate filaments

A part of the cytoskeleton that includes filaments intermediate in diameter between microtubules and microfilaments.

internal environment

In multicellular organisms, includes blood plasma and interstitial fluid (i.e., the extracellular fluids that surround the cells).

internal fertilization

The release of sperm into the female reproductive tract; typical of most terrestrial animals. (Contrast with external fertilization.)

internal gills

Gills enclosed in protective body cavities; typical of mollusks, arthropods, and fishes.

internal skeleton

See endoskeleton.

interneuron

A neuron that communicates information between two other neurons.

internode

The region between two nodes of a plant stem.

interphase

In the cell cycle, the period between successive nuclear divisions during which the chromosomes are diffuse and the nuclear envelope is intact. During interphase the cell is most active in transcribing and translating genetic information.

interspecific interactions

Interactions between members of two or more species.

interstitial fluid

Extracellular fluid that is not contained in the vessels of a circulatory system.

intertidal zone

A nearshore region of oceans that is periodically exposed to the air as the tides rise and fall.

intestine

The portion of the gut following the stomach, in which most digestion and absorption occurs.

intracellular receptor

A receptor that binds its ligand inside the cell. An example is the estrogen receptor in mammals.

intraspecific competition

Competition for shared limited resources by individuals of the same species.

intron

Portion of a gene within the coding region that is transcribed into pre-mRNA but is spliced out prior to translation. (Contrast with exon.)

invasive species

A non-native species that reproduces rapidly, spreads widely, and has mostly negative effects on the native species or ecosystems of the region to which it has been introduced.

inversion

A rare 180° reversal of the order of genes within a segment of a chromosome.

involution

Cell movements that occur during gastrulation of frog embryos, giving rise to the archenteron.

ion

(eye' on) [Gk. *ion*: wanderer] An electrically charged particle that forms when an atom gains or loses one or more electrons.

ion channel

An integral membrane protein that allows ions to diffuse across the membrane in which it is embedded.

ionic attraction

An electrostatic attraction between positively and negatively charged ions.

iris

(eye' ris) [Gk. *iris*: rainbow] The round, pigmented membrane that surrounds the pupil of the eye and adjusts its aperture to regulate the amount of light entering the eye.

islets of Langerhans

Clusters of hormone-producing cells in the pancreas.

isomers

Molecules consisting of the same numbers and kinds of atoms, but differing in the bonding patterns by which the atoms are held together.

isomorphic

(eye so more' fik) [Gk. *isos*: equal + *morphe*: form] Having the same form or appearance, as when the haploid and diploid life stages of an organism appear identical. (Contrast with heteromorphic.)

isotonic

Having the same solute concentration; said of two solutions. (Contrast with hypertonic, hypotonic.)

isotope

(eye' so tope) [Gk. *isos*: equal + *topos*: place] Isotopes of a given chemical element have the same number of protons in their nuclei (and thus are in the same position on the periodic table), but differ in the number of neutrons.

isozymes

Enzymes of an organism that have somewhat different amino acid sequences but catalyze the same reaction.

iteroparity

Reproducing multiple times in a lifetime. (Contrast with semelparity.)

J

jasmonic acid (jasmonate)

A plant hormone involved in triggering responses to pathogen attack as well as other processes.

jejunum

(jih jew' num) The middle division of the small intestine, where most absorption of nutrients occurs. (See *also* duodenum, ileum.)

joint

In skeletal systems, a junction between two or more bones.

juvenile hormone

In insects, a hormone maintaining larval growth and preventing maturation or pupation.

juxtacrine

A mode of cell communication where the cell producing a signal is in contact with the cell bearing the receptor for that signal.

K

K-strategist

A species whose life history strategy allows it to persist at or near the carrying capacity (K) of its environment. (Contrast with r -strategist.)

karyogamy

The fusion of nuclei of two cells. (Contrast with plasmogamy.)

karyotype

The number, forms, and types of chromosomes in a cell.

K_D

See dissociation constant.

keystone species

Species that have strong community-wide effects despite their small size and abundance.

kidneys

A pair of excretory organs in vertebrates.

kilocalorie (kcal)

See calorie.

kin selection

That component of inclusive fitness resulting from helping the survival of relatives containing the same alleles by descent from a common ancestor. (Contrast with direct fitness.)

kinetic energy

(kuh-net' ik) [Gk. *kinetos*: moving] The energy associated with movement.
(Contrast with potential energy.)

kinetochore

(kuh net' oh core) Specialized structure on a centromere to which microtubules attach.

Koch's postulates

A set of rules for establishing that a particular microorganism causes a particular disease.

L**lacteals**

The smallest vessels of the lymphatic system.

lactic acid fermentation

A metabolic pathway in which glucose is catabolized in the absence of oxygen with the production of lactic acid.

lagging strand

In DNA replication, the daughter strand that is synthesized in discontinuous stretches. (See Okazaki fragments. Contrast with leading strand.)

landscape

A geographic area consisting of multiple ecosystems or habitats.

larva

(plural: larvae) [L. *lares*: guiding spirits] An immature stage of any animal that differs dramatically in appearance from the adult.

larynx

A structure between the pharynx and trachea that contains the vocal cords.

lateral gene transfer

The transfer of genes from one species to another, common among bacteria and archaea.

lateral meristem

Either of the two meristems, the vascular cambium and the cork cambium, that give rise to a plant's secondary growth.

lateral root

A root extending outward from the taproot in a taproot system; typical of eudicots.

lateralization

A phenomenon in humans in which language functions come to reside in one cerebral hemisphere, usually the left.

laticifers

(luh tiss' uh furs) In some plants, elongated cells containing secondary plant products such as latex.

Laurasia

The northernmost of the two large continents produced by the breakup of Pangaea.

law of independent assortment

See independent assortment.

law of mass action

The rate of a chemical reaction is directly proportional to the concentrations of the reacting substances.

law of segregation

See segregation.

laws of thermodynamics

[Gk. *thermos*: heat + *dynamis*: power] Laws derived from studies of the physical properties of energy and the ways energy interacts with matter. (See *also* first law of thermodynamics, second law of thermodynamics.)

LDLs

See low-density lipoproteins.

LDP

See long-day plant.

leaching

In soils, a process by which mineral nutrients in upper soil horizons are dissolved in water and carried to deeper horizons, where they are unavailable to plant roots.

leading strand

In DNA replication, the daughter strand that is synthesized continuously. (Contrast with lagging strand.)

leaf

(plural: leaves) In plants, the chief organ of photosynthesis.

leaf primordium

(plural: primordia) An outgrowth on the side of the shoot apical meristem that will eventually develop into a leaf.

leghemoglobin

In nitrogen-fixing plants, an oxygen-carrying protein in the cytoplasm of nodule cells that transports enough oxygen to the nitrogen-fixing bacteria to support their respiration, while keeping free oxygen concentrations low enough to protect nitrogenase.

lek

A display ground within which male animals compete for and defend small display areas as a means of demonstrating their territorial prowess and winning opportunities to mate.

lens

In the vertebrate eye, a crystalline protein structure that makes fine adjustments in the focus of images falling on the retina.

lenticels

Small porous regions on the bark of woody stems and roots in dicots.

leptin

A hormone produced by fat cells that is believed to provide feedback information to the brain about the status of the body's fat reserves.

Leydig cells

The cells between the seminiferous tubules of the testes that secrete testosterone.

LH

See luteinizing hormone.

lichen

(lie' kun) An organism resulting from the symbiotic association of a fungus and either a cyanobacterium or a unicellular alga.

life history

The lifetime pattern of growth, reproduction, and survival for an average individual.

life history strategy

The way in which individuals within and among species allocate resources to growth, reproduction, and survival based on genetic and environmental factors.

life table

A summary of how survival and reproductive rates vary with the age, size, or sex of individuals within a population, and used to estimate population growth rate.

ligament

A band of connective tissue linking two bones in a joint.

ligand

(lig' and) Any molecule that binds to a receptor site of another (usually larger) molecule.

light reactions

The initial phase of photosynthesis, in which light energy is converted into chemical energy.

light-harvesting complex

In photosynthesis, a group of different molecules that cooperate to absorb light energy and transfer it to a reaction center. Also called antenna system.

light-independent reactions

Reactions that follow the light reaction and use the energy captured in the light reactions to drive the reduction of CO₂ to form carbohydrates.

lignin

A complex, hydrophobic polyphenolic polymer in plant cell walls that crosslinks other wall polymers, strengthening the walls, especially in wood.

limbic system

A group of evolutionarily primitive structures in the vertebrate telencephalon that are involved in emotions, drives, instinctive behaviors, learning, and memory.

limiting resource

The required resource whose supply (or lack thereof) most strongly influences the size of a population.

lineage

A series of populations, species, or genes descended from a single ancestor over evolutionary time.

lineage species concept

The definition of a species as a branch on the tree of life, which has a history that starts at a speciation event and ends either at extinction or at another speciation event. (Contrast with biological species concept, morphological species concept.)

linear regression

A statistical method of fitting a straight line to describe the relationship between two variables in a scatter plot.

linkage analysis

Genetic analysis in which a gene and its alleles are linked to an unknown gene and its alleles and the location of the latter is determined by its co-segregating with the former in genetic crosses.

lipases

Digestive enzymes that break down fats.

lipid

(lip' id) [Gk. *lipos*: fat] Nonpolar, hydrophobic molecules that include fats, oils, waxes, steroids, and the phospholipids that make up biological membranes.

lipid bilayer

See phospholipid bilayer.

lipoproteins

Lipids packaged inside a covering of protein so that they can be circulated in the blood.

liposome

(lip' o zome) Spherical structure contained by a membrane of phospholipids. Can be used to deliver drugs to cells.

lithosphere

(lith' o sphere) [Gk. *lithos*: strong] The crust of solid rock plates that overlays the viscous mantle of Earth. The movements of the lithosphere are the source of plate tectonics. (Contrast with asthenosphere.)

liver

A large digestive gland. In vertebrates, it secretes bile and is involved in the formation of blood.

loading

In phloem, the process of transferring the products of photosynthesis, usually sugars, into sieve tubes.

loam

A type of soil consisting of a mixture of sand, silt, clay, and organic matter. One of the best soil types for agriculture.

locus

(low' kus) (plural: loci, low' sigh) In genetics, a specific location on a chromosome. May be considered synonymous with gene.

logistic growth

A pattern of population growth characterized by a multiplicative pattern that eventually levels off as density dependent processes slow growth at some carrying capacity (Contrast with exponential growth.)

long-day plant (LDP)

A plant that requires long days (actually, short nights) in order to flower. (Compare to short-day plant.)

long-term depression (LTD)

A long-lasting decrease in the responsiveness of a neuron resulting from a period of prior stimulation. (Contrast with long-term potentiation.)

long-term memory

Information that is maintained in the brain and is accessible for long periods of time—hours to years. (Contrast with immediate memory, short-term memory.)

long-term potentiation (LTP)

A long-lasting increase in the responsiveness of a neuron resulting from a period of intense stimulation. (Contrast with long-term depression.)

loop of Henle

(hen' lee) Long, hairpin loop of the mammalian renal tubule that runs from the cortex down into the medulla and back to the cortex; creates a concentration

gradient in the interstitial fluids in the medulla.

lophophore

A U-shaped fold of the body wall with hollow, ciliated tentacles that encircles the mouth of animals in several different groups. Used for filtering prey from the surrounding water.

loss-of-function mutation

A mutation that results in the loss of a functional protein. (Contrast with gain-of-function mutation.)

lottery model

A hypothesis proposing that species diversity in communities is maintained by a “lottery” in which resources, made available by the effects of disturbance, stress, or predation, are captured at random by individuals of different species. Also called neutral model.

low-density lipoproteins (LDLs)

Lipoproteins that transport cholesterol around the body for use in biosynthesis and for storage; LDLs are the “bad” lipoproteins associated with a high risk of cardiovascular disease.

lower critical temperature

The environmental temperature at which a resting endotherm must increase its metabolic rate to avoid a drop in its body temperature.

lumen

(loo' men) [L. *lumen*: light] The open cavity inside any tubular organ or structure, such as the gut or a renal tubule.

lung

An internal organ specialized for respiratory gas exchange with air.

luteinizing hormone (LH)

A gonadotropin produced by the anterior pituitary that stimulates the gonads to produce sex hormones.

lymph

[L. *lympa*: liquid] A fluid derived from blood and other tissues that accumulates in intercellular spaces throughout the body and is returned to the blood by the lymphatic system.

lymph node

A specialized structure in the vessels of the lymphatic system. Lymph nodes contain lymphocytes, which encounter and respond to foreign cells and molecules in the lymph as it passes through the vessels.

lymphatic duct

One of two large lymphatic vessels that drains lymph into a subclavian vein.

lymphocyte

One of the two major classes of white blood cells; includes T cells, B cells, and other cell types important in the immune system.

lysogeny

A form of viral replication in which the virus becomes incorporated into the host chromosome and remains inactive. Also called a lysogenic cycle. (Contrast with lytic cycle.)

lysosome

(lie' so soam) [Gk. *lysis*: break away + *soma*: body] A membrane-enclosed organelle originating from the Golgi apparatus and containing hydrolytic enzymes. (Contrast with secondary lysosome.)

lysozyme

(lie' so zyme) An enzyme in saliva, tears, and nasal secretions that hydrolyzes bacterial cell walls.

lytic cycle

A viral reproductive cycle in which the virus takes over a host cell's synthetic machinery to replicate itself, then bursts (lyses) the host cell, releasing the new viruses. (Contrast with lysogeny.)

M**macroevolution**

[Gk. *makros*: large] Evolutionary changes occurring over long time spans and usually involving changes in many traits. (Contrast with microevolution.)

macroglia

Non-neuronal cells of the central and peripheral nervous system that provide homeostatic functions for neurons, modulate synaptic connections, provide myelin coverings for axons, and create the blood-brain or blood-spinal cord barrier.

macromolecule

A giant (molecular weight > 1,000) polymeric molecule. The macromolecules are the proteins, polysaccharides, and nucleic acids.

macronutrient

In plants, a mineral element required in concentrations of at least 1 milligram per gram of plant dry matter; in animals, a mineral element required in large amounts. (Contrast with micronutrient.)

macroparasites

Relatively large parasite species, such as arthropods and worms. (Compare with microparasites.)

MADS box

DNA-binding domain in many plant transcription factors that is active in development.

maintenance methylase

An enzyme that catalyzes the methylation of the new DNA strand when DNA is replicated.

major histocompatibility complex (MHC)

A complex of linked genes, with multiple alleles, that control a number of cell surface antigens that identify self and can lead to graft rejection.

malignant

Pertaining to a tumor that can grow indefinitely and/or spread from the original site of growth to other locations in the body. (Contrast with benign.)

malnutrition

A condition caused by lack of any essential nutrient.

Malpighian tubule

(mal pee' gy un) A type of protonephridium found in insects.

mandible

A crushing part of arthropod mouth parts, in mammals, the lower jaw bone, in birds the upper or lower part of the beak.

mantle

(1) In mollusks, a fold of tissue that covers the organs of the visceral mass and secretes the hard shell that is typical of many mollusks. (2) In geology, Earth's crust below the solid lithospheric plates.

mark-recapture method

A method of estimating population sizes of mobile organisms by capturing, marking, and releasing a sample of individuals, then capturing another sample at a later time.

mass

A measure of the quantity of matter present; the greater the mass, the greater the quantity of matter.

mass extinction event

A period of evolutionary history during which rates of extinction are much higher than during intervening times.

mass number

The sum of the number of protons and neutrons in an atom's nucleus.

mast cells

Cells, typically found in connective tissue, that release histamine in response to tissue damage.

maternal effect genes

Genes coding for morphogens that determine the polarity of the egg and larva in

fruit flies. Part of a developmental cascade that includes gap genes, pair rule genes, segment polarity genes, and Hox genes.

mating

The joining of individuals for the purpose of reproduction.

mating type

A particular strain of a species that is incapable of sexual reproduction with another member of the same strain but capable of sexual reproduction with members of other strains of the same species.

maximum likelihood

A statistical method of determining which of two or more hypotheses (such as phylogenetic trees) best fit the observed data, given an explicit model of how the data were generated.

mean

The sum of all values in a sample divided by the number of observations in the sample.

measures of center

Quantities that describe various aspects of the center of a group of observations.

measures of dispersion

Measures that quantify the dispersion of observations in a sample of observations.

mechanically gated channel

A molecular channel that opens or closes in response to mechanical force applied to the plasma membrane in which it is inserted.

mechanoreceptor

A cell that is sensitive to physical movement and generates action potentials in response.

median

The value at which there are equal numbers of larger and smaller observations in a sample.

medulla

(meh dull' luh) (1) The inner, core region of an organ, as in the adrenal medulla (adrenal gland) or the renal medulla (kidneys). (2) The portion of the brainstem that connects to the spinal cord.

medusa

(plural: medusae) In cnidarians, a free-swimming, sexual life cycle stage shaped like a bell or an umbrella.

megagametophyte

In heterosporous plants, the female gametophyte; produces eggs. (Contrast with

microgametophyte.)

megakaryocytes

A bone marrow cell that produces blood platelets.

megaphyll

The generally large leaf of a fern, horsetail, or seed plant, with several to many veins. (Contrast with microphyll.)

megasporangia

The plant structures that bear megaspores.

megaspore

[Gk. *megas*: large + *spora*: to sow] In plants, a haploid spore that produces a female gametophyte.

megastrobilus

In conifers, the female (seed-bearing) cone. (Contrast with microstrobilus.)

meiosis

(my oh' sis) [Gk. *meiosis*: diminution] Division of a diploid nucleus to produce four haploid daughter cells. The process consists of two successive nuclear divisions with only one cycle of chromosome replication. In meiosis I, homologous chromosomes separate but retain their chromatids. The second division meiosis II, is similar to mitosis, in which chromatids separate.

meiosis I

See meiosis.

meiosis II

See meiosis.

Meissner's corpuscles

Rapidly adapting skin mechanoreceptors sensitive to light touch and vibration. Found primarily in non-hairy skin; provide continuous information about changes in things touching the skin.

melanocyte-stimulating hormone (MSH)

A pituitary peptide hormone that stimulates melanocytes to produce the pigment melanin.

melatonin

A hormone released by the pineal gland. Involved in photoperiodicity and circadian rhythms.

membrane

A phospholipid bilayer forming a barrier that separates the internal contents of a cell from the nonbiological environment, or enclosing the organelles within a cell. The membrane regulates the molecular substances entering or leaving a cell or

organelle.

membrane potential

The difference in electrical charge between the inside and the outside of a cell, caused by a difference in the distribution of ions.

membranous bone

A type of bone that develops by forming on a scaffold of connective tissue. (Contrast with cartilage bone.)

memory cells

Long-lived lymphocytes produced after exposure to antigen. They persist in the body and are able to mount a rapid response to subsequent exposures to the antigen.

menopause

In human females, the end of fertility and menstrual cycling.

menstrual cycle

A term for the uterine cycle of humans that refers to the monthly sloughing of the uterine lining, or menses.

menstruation

The process by which the endometrium breaks down, and the sloughed-off tissue, including blood, flows from the body.

meristem

[Gk. *meristos*: divided] Plant tissue made up of undifferentiated actively dividing cells.

meristem culture

A method for the asexual propagation of plants, in which pieces of shoot apical meristem are cultured to produce plantlets.

meristem identity genes

In angiosperms, a group of genes whose expression initiates flower formation, probably by switching meristem cells from a vegetative to a reproductive fate.

Merkel's discs

Slowly adapting skin mechanoreceptors that provide continuous information about anything touching the skin.

mesenchyme

(mez' en kyme) [Gk. *mesos*: middle + *enchyma*: infusion] Embryonic or unspecialized cells derived from the mesoderm.

mesoderm

[Gk. *mesos*: middle + *derma*: skin] The middle of the three embryonic germ layers first delineated during gastrulation. Gives rise to the skeleton, circulatory system,

muscles, excretory system, and most of the reproductive system.

mesoglea

(mez' uh glee uh) [Gk. *mesos*: middle + *gloia*: glue] A thick, gelatinous noncellular layer that separates the two cellular tissue layers of ctenophores, cnidarians, and scyphozoans.

mesophyll

(mez' uh fill) [Gk. *mesos*: middle + *phyllon*: leaf] Chloroplast-containing, photosynthetic cells in the interior of leaves.

messenger RNA (mRNA)

Transcript of a region of one of the strands of DNA; carries information (as a sequence of codons) for the synthesis of one or more proteins.

metabolism

(meh tab' a lizm) [Gk. *metabole*: change] The sum total of the chemical reactions that occur in an organism, or some subset of that total (as in respiratory metabolism).

metabolome

The quantitative description of all the small molecules in a cell or organism.

metagenomics

The practice of analyzing DNA from environmental samples without isolating intact organisms.

metamorphosis

(met' a mor' fo sis) [Gk. *meta*: between + *morphe*: form, shape] A change occurring between one developmental stage and another, as for example from a tadpole to a frog. (See complete metamorphosis, incomplete metamorphosis.)

metanephridia

(singular: metanephridium) [Gk. *meta*: akin to] The paired excretory organs of annelids.

metapopulation

A group of geographically isolated populations linked together by dispersal.

metastasis

Spread of cells a tumor to regions of the body away from the primary tumor.

methanogens

Methane-producing microbes.

methylation

The addition of a methyl group (—CH_3) to a molecule.

MHC

See major histocompatibility complex.

MI

See myocardial infarction.

micelle

A particle of lipid covered with bile salts that is produced in the duodenum and facilitates digestion and absorption of lipids.

microbiome

The diverse community of bacteria that lives on or within the body of an organism and is essential to bodily function.

microbiota

The diverse communities of bacteria that live on or within the body.

microevolution

Evolutionary changes below the species level, affecting allele frequencies. (Contrast with macroevolution.)

microfilament

In eukaryotic cells, a fibrous structure made up of actin monomers. Microfilaments play roles in the cytoskeleton, in cell movement, and in muscle contraction.

microgametophyte

In heterosporous plants, the male gametophyte; produces sperm. (Contrast with megagametophyte.)

microglia

Glial cells that act as macrophages and mediators of inflammatory responses in the central nervous system.

micronutrient

In plants, a mineral element required in concentrations of less than 100 micrograms per gram of plant dry matter; in animals, a mineral element required in concentrations of less than 100 micrograms per day. (Contrast with macronutrient.)

microparasites

Parasite species too small to be seen with the naked eye, such as viruses, bacteria, protists, and fungi. (Compare with macroparasites.)

microphyll

A small leaf with a single vein, found in club mosses and their relatives. (Contrast with megaphyll.)

micropyle

(mike' roh pile) [Gk. *mikros*: small + *pylon*: gate] Opening in the integument(s) of a seed plant ovule through which pollen grows to reach the female gametophyte within.

microRNA (miRNA)

A small, noncoding RNA molecule, typically about 21 bases long, that binds to mRNA to inhibit its translation.

microsporangia

The plant structures that bear microspores.

microspore

[Gk. *mikros*: small + *spora*: to sow] In plants, a haploid spore that produces a male gametophyte.

microstrobilus

In conifers, male pollen-bearing cone. (Contrast with megastrobilus.)

microtubules

Tubular structures found in centrioles, spindle apparatus, cilia, flagella, and cytoskeleton of eukaryotic cells. These tubules play roles in the motion and maintenance of shape of eukaryotic cells.

microvilli

(singular: microvillus) Projections of epithelial cells, such as the cells lining the small intestine, that increase their surface area.

midbrain

One of the three regions of the vertebrate brain. Part of the brainstem, it serves as a relay station for sensory signals sent to the cerebral hemispheres. (Compare with forebrain, hindbrain.)

middle lamella

(la mell' ah) [L. *lamina*: thin sheet] A layer of polysaccharides that separates plant cells; a shared middle lamella lies outside the primary walls of the two cells.

migration

Roundtrip movement of individuals within a population as a consequence of seasonal variation in resources.

mineral nutrients

Inorganic ions required by organisms for normal growth and reproduction.

mineralization

The process by which animals, bacteria, and fungi convert organic compounds into inorganic soluble nutrients.

mismatch repair

A mechanism that scans DNA after it has been replicated and corrects any base-pairing mismatches.

missense mutation

A change in a gene's sequence that changes the amino acid at that site in the

encoded protein. (Contrast with frame-shift mutation, nonsense mutation, silent mutation.)

missense substitution

A change in a gene from one nucleotide to another that results in a change to the corresponding amino acid in the encoded protein. (Contrast with synonymous substitution.)

mitochondria

(my' toe kon' dree uh) (singular: mitochondrion) [Gk. *mitos*: thread + *chondros*: grain] Energy-generating organelles in eukaryotic cells that contain the enzymes of the citric acid cycle, the respiratory chain, and oxidative phosphorylation.

mitosis

(my toe' sis) [Gk. *mitos*: thread] Nuclear division in eukaryotes leading to the formation of two daughter nuclei, each with a chromosome complement identical to that of the original nucleus.

mitosomes

Reduced structures derived from mitochondria found in some organisms.

mitral valve

See bicuspid valve. So named because it has a similar shape to a miter (a religious headdress).

mode

The most frequent value in a sample of observations.

model organisms

Also known as **model systems**, these include the small group of species that are the subject of extensive research. They are organisms that adapt well to laboratory situations and findings from experiments on them can apply across a broad range of species. Classic examples include white mice and the fruit fly *Drosophila*.

moderately repetitive sequences

DNA sequences repeated 10–1,000 times in the eukaryotic genome. They include the genes that code for rRNAs and tRNAs, as well as the DNA in telomeres.

molds

Sac fungi composed of filamentous hyphae that do not form large ascomata.

mole

A quantity of a compound whose weight in grams is numerically equal to its molecular weight expressed in atomic mass units. Avogadro's number of molecules: 6.023×10^{23} molecules.

molecular clock

The approximately constant rate of divergence of macromolecules from one another over evolutionary time; used to date past events in evolutionary history.

molecular evolution

The scientific study of the mechanisms and consequences of the evolution of macromolecules.

molecular weight

The sum of the atomic weights of the atoms in a molecule.

molecule

A chemical substance made up of two or more atoms joined by covalent bonds or ionic attractions.

molting

The process of shedding part or all of an outer covering, as the shedding of feathers by birds or of the entire exoskeleton by arthropods.

monoblastic

Having a body derived from a single embryonic cell layer. (Contrast with diploblastic, triploblastic.)

monocots

Angiosperms with a single embryonic cotyledon; one of the two largest clades of angiosperms. (See *also* eudicots.)

monoculture

In agriculture, a large-scale planting of a single crop species. (Contrast with polyculture).

monoecious

(mo nee' shus) [Gk. *mono*: one + *oikos*: house] Pertaining to organisms in which both sexes are "housed" in a single individual that produces both eggs and sperm. (In some plants, these are found in different flowers within the same plant.) Examples include corn, peas, earthworms, hydras. (Contrast with dioecious.)

monohybrid cross

A mating in which the parents differ with respect to the alleles of only one locus of interest.

monomer

[Gk. *mono*: one + *meros*: unit] A small molecule, two or more of which can be combined to form oligomers (consisting of a few monomers) or polymers (consisting of many monomers).

monophyletic

(mon' oh fih leht' ik) [Gk. *mono*: one + *phylon*: tribe] Pertaining to a group that consists of an ancestor and all of its descendants. (Contrast with paraphyletic, polyphyletic.)

monosaccharide

A simple sugar. Oligosaccharides and polysaccharides are made up of

monosaccharides.

monosomic

Pertaining to an organism with one less than the normal diploid number of chromosomes.

morphogen

A diffusible substance whose concentration gradient determines a developmental pattern in embryonic animals and plants.

morphogenesis

(more' fo jen' e sis) [Gk. *morphe*: form + *genesis*: origin] The development of form; the overall consequence of determination, differentiation, and growth.

morphological species concept

The definition of a species as a group of individuals that look alike. (Contrast with biological species concept, lineage species concept.)

morphology

(more fol' o jee) [Gk. *morphe*: form + *logos*: study, discourse] The scientific study of organic form, including both its development and function.

mosaic development

Pattern of animal embryonic development in which each blastomere contributes a specific part of the adult body. (Contrast with regulative development.)

motile

(mo' tul) Able to move from one place to another. (Contrast with sessile.)

motor cortex

The region of the cerebral cortex that contains motor neurons that directly stimulate specific muscle fibers to contract.

motor end plate

The depression in the postsynaptic membrane of the neuromuscular junction where the terminals of the motor neuron sit.

motor proteins

Specialized proteins that use energy to change shape and move cells or structures within cells.

motor unit

A motor neuron and the muscle fibers it controls.

MSH

See melanocyte-stimulating hormone.

mucosa

The first layer of the gut that lines the luminal surface.

mucus

A viscous substance secreted by mucous membranes (e.g., mucosal epithelium). A barrier defense against pathogens in innate immunity in animals and a protective coating in many animal organ systems.

Muller's ratchet

The accumulation—“ratcheting up”—of deleterious mutations in the nonrecombining genomes of asexual species.

Müllerian mimicry

Convergence in appearance of two or more unpalatable species.

multifactorial

The interaction of many genes and proteins with one or more factors in the environment. For example, cancer is a disease with multifactorial causes.

multiple fruits

A fruit that develops from several carpels of multiple flowers.

multiplication rule

The probability of two or more independent events occurring together is the product of their independent probabilities.

multipotent

Having the ability to differentiate into a limited number of cell types. (Contrast with pluripotent, totipotent, unipotent.)

muscle fiber

A single muscle cell. In the case of skeletal muscle, a syncytial, multinucleate cell.

muscle spindles

Mechanoreceptors embedded in skeletal muscle that sense changes in the length of the muscle.

muscle tissue

Excitable tissue that can contract through the interactions of actin and myosin; one of the four major tissue types in multicellular animals. There are three types of muscle tissue: skeletal, smooth, and cardiac.

mutagen

(mute' ah jen) [L. *mutare*: change + Gk. *genesis*: source] Any agent (e.g., a chemical, radiation) that increases the mutation rate.

mutation

A change in the genetic material not caused by recombination.

mutualism

A type of positive interaction in which both species benefit from the interaction, sometimes in a highly dependent and symbiotic manner. (Contrast with

amensalism, commensalism, competition.)

mycelium

(my seel' ee yum) [Gk. *mykes*: fungus] In the fungi, a mass of hyphae.

mycologists

Scientists who study fungi.

mycorrhiza

(my' ko rye' za) (plural: mycorrhizae) [Gk. *mykes*: fungus + *rhiza*: root] An association of the root of a plant with the mycelium of a fungus.

myelin

(my' a lin) Concentric layers of plasma membrane that form a sheath around some axons; myelin provides the axon with electrical insulation and increases the rate of transmission of action potentials.

myocardial infarction (MI)

Blockage of an artery that carries blood to the heart muscle; a "heart attack."

MyoD

The protein encoded by the *myoblast determining* gene. A transcription factor involved in the differentiation of myoblasts (muscle precursor cells).

myofibril

(my' oh fy' bril) [Gk. *mys*: muscle + L. *fibrilla*: small fiber] A polymeric unit of actin or myosin in a muscle.

myoglobin

(my' oh globe' in) [Gk. *mys*: muscle + L. *globus*: sphere] An oxygen-binding molecule found in muscle. Consists of a heme unit and a single globin chain; carries less oxygen than hemoglobin.

myosin

One of the two contractile proteins of muscle. (See *also* actin.)

myxamoeba

An independent, unicellular, haploid life stage of cellular slime molds.

N

natural killer cell

A type of lymphocyte that attacks virus-infected cells and some tumor cells as well as antibody-labeled target cells.

natural selection

The differential contribution of offspring to the next generation by various genetic types belonging to the same population. The mechanism of evolution proposed by Charles Darwin.

nauplius

(naw' plee us) [Gk. *nauplios*: shellfish] A bilaterally symmetrical larval form typical of crustaceans.

necrosis

(nec roh' sis) [Gk. *nekros*: death] Premature cell death caused by external agents such as toxins.

negative feedback

In regulatory systems, information that decreases a regulatory response, returning the system to the set point. (Contrast with positive feedback.)

negative regulation

A type of gene regulation in which a gene is normally transcribed, and the binding of a repressor protein to the promoter prevents transcription. (Contrast with positive regulation.)

negative-sense RNA

A strand of RNA that is complementary to mRNA.

nematocyst

(ne mat' o sist) [Gk. *nema*: thread + *kystis*: cell] An elaborate, threadlike structure produced by cells of jellyfishes and other cnidarians, used chiefly to paralyze and capture prey.

neoteny

(knee ot' enny) [Gk. *neo*: new, recent + *tenein*: to extend] The retention of juvenile or larval traits by the fully developed adult organism.

nephron

(nef' ron) [Gk. *nephros*: kidney] The functional unit of the kidney, consisting of a structure for receiving a filtrate of blood and a tubule that reabsorbs selected parts of the filtrate.

Nernst equation

A mathematical statement that calculates the potential across a membrane permeable to a single type of ion that differs in concentration on the two sides of the membrane.

nerve

A structure consisting of many neuronal axons and connective tissue.

nerve nets

Diffuse, loosely connected aggregations of nervous tissues in certain non-bilatarian animals such as cnidarians.

nervous tissue

Tissue specialized for processing and communicating information; one of the four major tissue types in multicellular animals.

net primary production (NPP)

The amount of energy or biomass incorporated into the tissues of primary producers after respiration. (Compare with gross primary production.)

net reproductive rate (R_0)

The mean number of offspring produced by an individual in a population during its lifetime.

net secondary production

The amount of energy or biomass obtained from the consumption and assimilation of other organisms, taking into account respiration.

neural crest cells

During vertebrate neurulation, cells that migrate outward from the neural plate and give rise to connections between the central nervous system and the rest of the body.

neural network

An organized group of neurons that contains three functional categories of neurons—afferent neurons, interneurons, and efferent neurons—and is capable of processing information.

neural tube

An early stage in the development of the vertebrate nervous system consisting of a hollow tube created by two opposing folds of the dorsal ectoderm along the anterior–posterior body axis.

neurohormone

A chemical signal produced and released by neurons that subsequently acts as a hormone.

neuromuscular junction

Synapse (point of contact) where a motor neuron axon stimulates a muscle fiber cell.

neuron

(noor' on) [Gk. *neuron*: nerve] A nervous system cell that can generate and conduct action potentials along an axon to a synapse with another cell.

neurotransmitter

A substance produced in and released by a neuron (the presynaptic cell) that diffuses across a synapse and excites or inhibits another cell (the postsynaptic cell).

neurulation

Stage in vertebrate development during which the nervous system begins to form.

neutral allele

An allele that does not alter the functioning of the proteins for which it codes.

neutral model

See lottery model.

neutral theory

A view of molecular evolution that postulates that most mutations do not affect the amino acid being coded for, and that such mutations accumulate in a population at rates driven by genetic drift and mutation rates.

neutron

(new' tron) One of the three fundamental particles of matter (along with protons and electrons), with mass slightly larger than that of a proton and no electrical charge.

niche

(nitch) [L. *nidus*: nest] The set of physical and biological conditions a species requires to grow, reproduce, and survive.

nitrate reduction

The process by which nitrate (NO_3^-) is reduced to ammonia (NH_3).

nitrification

The oxidation of ammonia (NH_3) to nitrate (NO_3^-) in soil and seawater, carried out by chemoautotrophic bacteria (nitrifiers).

nitrifiers

Prokaryotes that can convert ammonium into nitrate.

nitrogen fixation

Conversion of atmospheric nitrogen gas (N_2) into a more reactive and biologically useful form (ammonia), which makes nitrogen available to living things. Carried out by nitrogen fixers—bacteria, some of them free-living and others living within plant roots.

nitrogen fixers

Organisms capable of fixing atmospheric N_2 to form NH_3 .

nitrogenase

An enzyme complex found in nitrogen-fixing bacteria that mediates the stepwise reduction of atmospheric N_2 to ammonia and which is strongly inhibited by oxygen.

node

[L. *nodus*: knob, knot] (1) In plants, a (sometimes enlarged) point on a stem where a leaf is or was attached. (2) A region at the anterior end of the primitive groove—the site of ingression of cells during gastrulation. In mammals and birds it serves a function similar to the dorsal lip of the blastopore in amphibians.

node of Ranvier

A gap in the myelin sheath covering an axon; the point where the axonal

membrane can fire action potentials.

non-disjunction

Failure of sister chromatids to separate in meiosis II or mitosis, or failure of homologous chromosomes to separate in meiosis I. Results in aneuploidy.

non-REM sleep

A state of deep, restorative sleep characterized by high-amplitude slow waves in the EEG. (Contrast with REM sleep.)

noncompetitive inhibitor

A nonsubstrate that inhibits the activity of an enzyme by binding to a site other than its active site. (Contrast with competitive inhibitor.)

noncyclic electron transport

In photosynthesis, the flow of electrons that forms ATP, NADPH, and O₂.

nonpolar

Having electric charges that are evenly balanced from one end to the other. (Contrast with polar.)

nonpolar covalent bond

A covalent bond between atoms that has equal sharing of electrons.

nonsense mutation

Change in a gene's sequence that prematurely terminates translation by changing one of its codons to a stop codon. (Contrast with frame-shift mutation, missense mutation, silent mutation.)

nonsense substitution

A change in a gene from one nucleotide to another that prematurely terminates translation by changing one of its codons to a stop codon. (Contrast with synonymous substitution.)

nonsynonymous substitution

A change in a gene from one nucleotide to another that changes the amino acid specified by the corresponding codon (i.e., AGC → AGA, or serine → arginine). (Contrast with synonymous substitution.)

nonvascular land plants

All land plants that lack a vascular system.

norepinephrine

A neurotransmitter found in the central nervous system and also at the postganglionic nerve endings of the sympathetic nervous system. Also called noradrenaline.

notochord

(no' tow kord) [Gk. *notos*: back + *chorde*: string] A flexible rod of gelatinous material

serving as a support in the embryos of all chordates and in the adults of tunicates and lancelets.

nuclear envelope

A double membrane that encloses the cell nucleus.

nucleases

Digestive enzymes that break down nucleic acids.

nucleic acid

(new klay' ik) A polymer made up of nucleotides, specialized for the storage, transmission, and expression of genetic information. DNA and RNA are nucleic acids.

nucleic acid hybridization

A technique in which a single-stranded nucleic acid probe is made that is complementary to, and binds to, a target sequence, either DNA or RNA. The resulting double-stranded molecule is a hybrid.

nucleoid

(new' klee oid) The region that harbors the chromosomes of a prokaryotic cell. Unlike the eukaryotic nucleus, it is not bounded by a membrane.

nucleolus

(new klee' oh lus) A small, generally spherical body found within the nucleus of eukaryotic cells. The site of synthesis of ribosomal RNA.

nucleoside

A nucleotide without the phosphate group; a nitrogenous base attached to a sugar.

nucleosome

A portion of a eukaryotic chromosome, consisting of part of the DNA molecule wrapped around a group of histone molecules, and held together by another type of histone molecule. The chromosome is made up of many nucleosomes.

nucleotide

The basic chemical unit in nucleic acids, consisting of a pentose sugar, a phosphate group, and a nitrogen-containing base.

nucleus

(new' klee us) [L. *nux*: kernel or nut] (1) In cells, the centrally located compartment of eukaryotic cells that is bounded by a double membrane and contains the chromosomes. (2) In the brain, an identifiable group of neurons that share common characteristics or functions.

null hypothesis

In statistics, the premise that any differences observed in an experiment are simply the result of random differences that arise from drawing two finite samples from the same population.

nutrient

A food substance; or, in the case of mineral nutrients, an inorganic element required for completion of the life cycle of an organism.

O**obligate**

A type of species interaction that is necessary to at least one species involved in the interaction. (Compare with facultative.)

obligate aerobe

An organism that requires an oxygen atmosphere to live.

obligate anaerobe

An anaerobic prokaryote that cannot survive exposure to O₂. (Compare with facultative anaerobe.)

obligate parasites

Organisms that can only survive and grow in or on other living organisms, to the detriment of the host.

occipital lobe

One of the four lobes of the brain's cerebral hemisphere; processes visual information.

ocean zone

The marine life zone that extends from the coastal zone into open ocean. Characterized by deep water that varies in its oxygenation and relatively stable temperatures and salinities.

odorant

A molecule that can bind to an olfactory receptor.

oil

A triglyceride that is liquid at room temperature. (Contrast with fat.)

Okazaki fragments

Newly formed DNA making up the lagging strand in DNA replication. DNA ligase links Okazaki fragments together to give a continuous strand.

olfaction

(ole fak' shun) [L. *olfacere*: to smell] The sense of smell.

olfactory bulb

Structure in the vertebrate forebrain that receives and processes input from olfactory receptor neurons.

olfactory receptor neurons (ORNs)

Neurons with receptors for different odorants.

oligodendrocyte

A type of glial cell that myelinates axons in the central nervous system.

oligosaccharide

A polymer containing a small number of monosaccharides.

omasum

The third of the four chambers of the stomach in ruminants; concentrates food by water absorption before it enters the true stomach (abomasum).

ommatidia

[Gk. *omma*: eye] The units that make up the compound eye of some arthropods.

omnivore

[L. *omnis*: everything + *vorare*: to devour] An organism that feeds on multiple trophic levels; also an organism that feeds on animals and primary producers. (Contrast with carnivore, detritivore, herbivore.)

omnivory

An act of predation in which the predator is animal and the prey is an animal or a plant. (Contrast with carnivory, herbivory, parasitism.)

oncogene

[Gk. *onkos*: mass, tumor + *genes*: born] A gene that codes for a protein product that stimulates cell proliferation. Mutations in oncogenes that result in excessive cell proliferation can give rise to cancer.

one gene–one polypeptide

The idea, now known to be an oversimplification, that each gene in the genome encodes only a single polypeptide—that there is a one-to-one correspondence between genes and polypeptides.

one-gene, one-enzyme hypothesis

See one gene–one polypeptide.

one-gene, one-polypeptide relationship

See one gene–one polypeptide.

oogonium

(oh' eh go' nee um) (plural: oogonia) (1) In some algae and fungi, a cell in which an egg is produced. (2) In animals, the diploid progeny of a germ cell in females.

ootid

In oogenesis, the daughter cell of the second meiotic division that differentiates into the mature ovum.

open circulatory system

Circulatory system in which extracellular fluid leaves the vessels of the circulatory system, percolates between cells and through tissues, and then flows back into the

circulatory system to be pumped out again. (Contrast with closed circulatory system.)

operant conditioning

Using a reward or a punishment to control the expression of a behavior by an animal in response to an unrelated stimulus.

operator

The region of an operon that acts as the binding site for the repressor.

operon

A genetic unit of transcription, typically consisting of several structural genes that are transcribed together; the operon contains at least two control regions: the promoter and the operator.

opportunity cost

The sum of the benefits an animal forfeits by not being able to perform some other behavior during the time when it is performing a given behavior. (Compare with energetic cost, risk cost.)

opsin

(op' sin) [Gk. *opsis*: sight] The protein portion of vertebrate visual pigments; associated with the pigment molecule 11-*cis*-retinal. (See *also* rhodopsin.)

optic chiasm

[Gk. *chiasma*: cross] Structure on the lower surface of the vertebrate brain where the two optic nerves come together.

optic nerve

The nerve that carries information from the retina of the eye to the brain.

optical isomers

Two molecular isomers that are mirror images of each other.

optimal foraging theory

The application of a cost–benefit approach to feeding behavior to identify the fitness value of feeding choices.

oral

[L. *os*: mouth] Pertaining to the mouth, or that part of the body that contains the mouth.

orbital

A region in space surrounding the atomic nucleus in which an electron is most likely to be found.

ordinal variables

Categorical variables with a natural ordering, such as the grades A, B, C, D, and F.

organ

[Gk. *organon*: tool] A body part, such as the heart, liver, brain, root, or leaf. Organs are composed of different tissues integrated to perform a distinct function. Organs, in turn, are integrated into organ systems.

organ identity genes

In angiosperms, genes that specify the different organs of the flower. (Compare with homeotic genes.)

organ of Corti

Structure in the inner ear that transforms mechanical forces produced from pressure waves ("sound waves") into action potentials that are sensed as sound.

organ system

An interrelated and integrated group of tissues and organs that work together in a physiological function.

organelle

(or gan el') Any of the membrane-enclosed structures within a eukaryotic cell. Examples include the nucleus, endoplasmic reticulum, and mitochondria.

organic fertilizers

Substances added to soil to improve the soil's fertility; derived from partially decomposed plant material (compost) or animal waste (manure).

organizer

Region of the early amphibian embryo that directs early embryonic development. Also known as the primary embryonic organizer.

organogenesis

The formation of organs and organ systems during development.

origin of replication (*ori*)

DNA sequence at which helicase unwinds the DNA double helix and DNA polymerase binds to initiate DNA replication.

ortholog

[Gk. *ortho*: true, direct] Homologous gene whose divergence can be traced to speciation events. (Contrast with paralog.)

osmoconformer

An aquatic animal that equilibrates the osmolarity of its extracellular fluid to be the same as that of the external environment. (Contrast with osmoregulator.)

osmolarity

The concentration of osmotically active particles in a solution.

osmoregulator

An aquatic animal that actively regulates the osmolarity of its extracellular fluid. (Contrast with osmoconformer.)

osmosis

(oz mo' sis) [Gk. *osmos*: to push] Movement of water across a differentially permeable membrane, from one region to another region where the water potential is more negative.

ossicles

Three bones in the middle ear that transmit vibrations from tympanum to the oval window of the inner ear. Individually named the malleus ("hammer"), incus ("anvil"), and stapes ("stirrup").

osteoblast

(oss' tee oh blast) [Gk. *osteon*: bone + *blastos*: sprout] A cell that lays down the protein matrix of bone.

osteoclast

(oss' tee oh clast) [Gk. *osteon*: bone + *klastos*: broken] A cell that dissolves bone.

osteocyte

(oss' tee oh site) [Gk. *osteon*: bone + *kytos*: cell] An osteoblast that has become enclosed in lacunae within the bone it has built.

otoliths

(oh' teliths) [Gk. *ous*: ear + *lithos*: stones] Crystals of calcium carbonate in the inner ear. Also called ear stones.

outgroup

In phylogenetics, a group of organisms used as a point of reference for comparison with the groups of primary interest (the ingroup).

oval window

The flexible membrane that, when moved by the bones of the middle ear, produces pressure waves in the inner ear.

ovarian cycle

(oh var' ee un) In human females, the monthly cycle of events by which eggs and hormones are produced. (Contrast with uterine cycle).

ovary

(oh' var ee) [L. *ovum*: egg] Any female organ, in plants or animals, that produces an egg.

overtopping

Plant growth pattern in which one branch differentiates from and grows beyond the others.

oviduct

In mammals, the tube serving to transport eggs to the uterus or to the outside of the body.

oviparity

Reproduction in which eggs are released by the female and development is external to the mother's body. (Contrast with viviparity.)

ovoviviparity

Pertaining to reproduction in which fertilized eggs develop and hatch within the mother's body but are not attached to the mother by means of a placenta.

ovulation

Release of an egg from an ovary.

ovule

(oh' vule) In plants, a structure comprising the megasporangium and the integument, which develops into a seed after fertilization.

ovum

(oh' vum) (plural: ova) [L. egg] The female gamete.

oxaloacetate

Four-carbon salt of an acid with the formula $\text{HOOC}-\text{CO}-\text{CO}-\text{COOH}$ that is an intermediate in metabolic pathways such as the citric acid cycle.

oxidation

(ox i day' shun) Relative loss of electrons in a chemical reaction; either outright removal to form an ion, or the sharing of electrons with substances having a greater affinity for them, such as oxygen. Most oxidations, including biological ones, are associated with the liberation of energy. (Contrast with reduction.)

oxidation–reduction (redox) reaction

A reaction in which one substance transfers one or more electrons to another substance. (See oxidation, reduction.)

oxidative phosphorylation

ATP formation in the mitochondrion, associated with flow of electrons through the respiratory chain.

oxygenase

An enzyme that catalyzes the addition of oxygen to a substrate from O_2 .

oxytocin

A hormone released by the posterior pituitary that promotes social bonding.

P**P-value**

The calculated probability of observing a given result by chance sampling, given the null hypothesis is true.

pacemaker cells

Cardiac cells that can initiate action potentials without stimulation from the nervous

system, allowing the heart to initiate its own contractions.

Pacinian corpuscles

(puh sin' ee uhn) Encapsulated mechanoreceptors in deep skin sensitive to pressure and vibration.

pair rule genes

In *Drosophila* (fruit fly) development, segmentation genes that divide the early embryo into units of two segments each. Part of a developmental cascade that includes maternal effect genes, gap genes, segment polarity genes, and Hox genes.

pancreas

(pan' cree us) A gland located near the stomach of vertebrates that secretes digestive enzymes into the small intestine and releases insulin into the bloodstream.

parabronchi

Passages in the lungs of birds through which air flows.

paracrine

[Gk. *para*: near] Pertaining to a chemical signal, such as a hormone, that acts locally, near the site of its secretion. (Contrast with autocrine.)

parallel evolution

The repeated evolution of similar traits, especially among closely related species; facilitated by conserved developmental genes.

paralog

Homologous gene whose divergence can be traced to gene duplication events. (Contrast with ortholog.)

paraphyletic

(par' a fih leht' ik) [Gk. *para*: beside + *phylon*: tribe] Pertaining to a group that consists of an ancestor and some, but not all, of its descendants. (Contrast with monophyletic, polyphyletic.)

parasite

[Gk. *parasitos*: one who eats at another's table] An organism that kills and/or consumes parts of an organism much larger than itself (known as its host). Parasites sometimes, but not always, kill their host.

parasitic plants

Plants that obtains some of their nutrition by growing on other plants.

parasitism

An act of predation in which the predator (a parasite) lives symbiotically on or in the prey (its host) and consumes only certain tissues without necessarily killing the host. (Contrast with carnivory, herbivory, omnivory.)

parasympathetic nervous system

The division of the autonomic nervous system that works in opposition to the sympathetic nervous system. (Contrast with sympathetic nervous system.)

parathyroid glands

Four glands on the posterior surface of the thyroid gland that produce and release parathyroid hormone.

parathyroid hormone (PTH)

A hormone secreted by the parathyroid glands that stimulates osteoclast activity and raises blood calcium levels. Also called parathormone. (Contrast with calcitonin.)

parenchyma

(pair eng' kyma) A plant tissue composed of relatively unspecialized cells without secondary walls. (Contrast with collenchyma, sclerenchyma.)

parent rock

The soil horizon consisting of the rock that is breaking down to form the soil. Also called bedrock, or the C horizon.

parental (P) generation

The individuals that mate in a genetic cross. Their offspring are the first filial (F_1) generation.

parietal cells

One of three types of secretory cell found in the gastric pits of the stomach wall. Parietal cells produce hydrochloric acid (HCl), creating an acidic environment that destroys many of the harmful microorganisms ingested with food. (See chief cells.)

parietal lobe

One of four lobes of the cerebral hemisphere; processes complex stimuli and includes the primary somatosensory cortex.

parsimony principle

Preferring the simplest among a set of plausible explanations of any phenomenon.

parthenocarpy

Formation of fruit from a flower without fertilization.

parthenogenesis

[Gk. *parthenos*: virgin] Production of an organism from an unfertilized egg.

partial pressures

In a mixture of gasses at a specific pressure, the contribution of each gas to that total pressure.

passive transport

Diffusion across a membrane; may or may not require a channel or carrier protein.

(Contrast with active transport.)

patch clamping

Technique for isolating a tiny patch of membrane to allow the study of ion movement through a particular channel.

pathogen

(path' o jen) [Gk. *pathos*: suffering + *genesis*: source] An organism that causes disease.

pathogen associated molecular patterns (PAMPs)

The molecules recognized by pattern recognition receptors.

pathogenesis-related (PR) protein

A plant protein involved in systemic acquired resistance whose synthesis is induced in response to an infection by a pathogen such as a fungus.

pattern formation

In animal embryonic development, the organization of differentiated tissues into specific structures such as wings.

pattern recognition receptors (PRRs)

Proteins expressed by cells of the innate immune system in animals or plants that bind to molecules from pathogens containing pathogen associated molecular patterns (PAMPs).

PCR

See polymerase chain reaction.

peat

Partly decomposed vegetable matter, especially of sphagnum moss, that is typically formed in acidic bogs.

pedigree

The pattern of transmission of a genetic trait within a family.

penetrance

The proportion of individuals with a particular genotype that show the expected phenotype.

penis

An accessory sex organ of male animals that enables the male to deposit sperm in the female's reproductive tract.

pentaradial symmetry

Symmetry in five or multiples of five; a feature of adult echinoderms.

pentose

[Gk. *penta*: five] A sugar containing five carbon atoms.

PEP carboxylase

The enzyme that combines carbon dioxide with PEP to form a 4-carbon dicarboxylic acid at the start of C₄ photosynthesis or of crassulacean acid metabolism (CAM).

peptidases

Digestive enzymes that break down peptides.

peptide hormones

Hormone molecules made up of chains of 2 to 50 amino acids (upper size arbitrary); encoded by genes and produced by translation.

peptide linkage

The bond between amino acids in a protein; formed between a carboxyl group and amino group (—CO—NH—) with the loss of water molecules.

peptidoglycan

The cell wall material of many bacteria, consisting of a single enormous molecule that surrounds the entire cell.

peptidyl transferase

A catalytic function of the large ribosomal subunit that consists of two reactions: breaking the bond between an amino acid and its tRNA in the P site, and forming a peptide bond between that amino acid and the amino acid attached to the tRNA in the A site.

per capita birth rate (*b*)

In population growth models, the average number of offspring that an individual produces over some time interval.

per capita death rate (*d*)

In population growth models, the average individual's chance of dying in some time interval.

per capita growth rate (*r*)

In population models, the average individual's contribution to total population growth rate. In mathematical terms, the difference between per capita birth rate (*b*) and per capita death rate (*d*) or (*b-d*).

perennial

(per ren' ee al) [L. *per*: throughout + *annus*: year] A plant that survives from year to year. (Contrast with annual, biennial.)

perfect flower

A flower with both stamens and carpels; a hermaphroditic flower. (Contrast with imperfect flower.)

pericycle

[Gk. *peri*: around + *kyklos*: ring or circle] In plant roots, tissue just within the

endodermis, but outside of the root vascular tissue. Meristematic activity of pericycle cells produces lateral root primordia.

periderm

The outer tissue of the secondary plant body, consisting primarily of cork.

period

(1) A category in the geological time scale. (2) The duration of a single cycle in a cyclical event, such as a circadian rhythm.

periodic table

The arrangement of elements in order of increasing atomic number, with vertical groupings of similar valence electrons.

peripheral membrane proteins **Proteins**

associated with but not embedded within the plasma membrane. (Contrast with integral membrane proteins.)

peripheral nervous system (PNS)

The portion of the nervous system that transmits information to and from the central nervous system, consisting of neurons that extend or reside outside the brain or spinal cord and their supporting cells. (Contrast with central nervous system.)

peristalsis

(pair' i stall' sis) Wavelike muscular contractions proceeding along a tubular organ, propelling the contents along the tube.

peritoneum

The mesodermal lining of the body cavity in coelomate animals.

peritubular capillaries

Small blood vessels that surround the renal tubules.

peroxisome

An organelle that houses reactions in which toxic peroxides are formed and then converted to water.

petal

[Gk. *petalon*: spread out] In an angiosperm flower, a sterile modified leaf, nonphotosynthetic, frequently brightly colored, and often serving to attract pollinating insects.

P_{fr}

See phytochrome.

pH

The negative logarithm of the hydrogen ion concentration; a measure of the acidity of a solution. A solution with pH = 7 is said to be neutral; pH values higher than 7

characterize basic solutions, while acidic solutions have pH values less than 7.

phage therapy

The therapeutic use of bacteriophages to treat pathogenic bacterial infections.

phagocyte

[Gk. *phagein*: to eat + *kystos*: sac] One of two major classes of white blood cells; one of the nonspecific defenses of animals; ingests invading microorganisms by phagocytosis.

phagocytosis

The process by which a cell uses its cell membrane to enclose and engulf a macromolecule or particle in the extracellular environment.

pharmacogenomics

The study of how an individual's genetic makeup affects his or her response to drugs or other agents, with the goal of predicting the effectiveness of different treatment options.

pharming

The use of genetically modified animals to produce medically useful products in their milk.

pharynx

[Gk. throat] The part of the gut between the mouth and the esophagus.

phenotype

(fee' no type) [Gk. *phanein*: to show] The observable properties of an individual resulting from both genetic and environmental factors. (Contrast with genotype.)

pheromone

(feer' o mone) [Gk. *pheros*: carry + *hormon*: excite, arouse] A chemical substance used in communication between organisms of the same species.

phloem

(flo' um) [Gk. *phloos*: bark] In vascular plants, the vascular tissue that transports sugars and other solutes from sources to sinks.

phloem sap

Liquid contents on the phloem tubes.

phosphatidyl inositol-bisphosphate (PIP₂)

A phospholipid in the cell membrane that is involved in cell signaling after a ligand binds to a nearby receptor.

phosphodiester linkage

The connection in a nucleic acid strand, formed by linking two nucleotides.

phosphoenolpyruvate (PEP)

Phosphorylated salt of a three-carbon acid, formula $\text{OPO}_3\text{H}_2\text{—CO—CO—COOH}$ that is an intermediate in metabolic pathways such as glycolysis.

phospholipid

A lipid containing a phosphate group; an important constituent of cellular membranes. (See lipid.)

phospholipid bilayer

The basic structural unit of biological membranes; a sheet of phospholipids two molecules thick in which the phospholipids are lined up with their hydrophobic “tails” packed tightly together and their hydrophilic, phosphate-containing “heads” facing outward. Also called lipid bilayer.

phosphorylation

Addition of a phosphate group.

photic zone

The life zone in lakes and oceans that is penetrated by light and therefore supports photosynthetic organisms.

photoautotroph

An organism that obtains energy from light and carbon from carbon dioxide. (Contrast with chemoautotroph, chemoheterotroph, photoheterotroph.)

photoheterotroph

An organism that obtains energy from light but must obtain its carbon from organic compounds. (Contrast with chemoautotroph, chemoheterotroph, photoautotroph.)

photomorphogenesis

In plants, a process by which physiological and developmental events are controlled by light.

photon

(foe' ton) [Gk. *photos*: light] A quantum of visible radiation; a “packet” of light energy.

photoperiodism

Control of an organism's physiological or behavioral responses by the length of the day or night (the photoperiod).

photophosphorylation

Mechanism for ATP formation in chloroplasts in which electron transport is coupled to the transport of hydrogen ions (protons, H^+) across the thylakoid membrane. (Compare with chemiosmosis.)

photoreceptors

(1) In plants, pigments that trigger a physiological response when they absorb a photon. (2) In animals, the sensory receptor cells that sense and respond to light energy. (See cone cells, rod cells.)

photorespiration

Light-driven uptake of oxygen and release of carbon dioxide, the carbon being derived from the early reactions of photosynthesis.

photosensitivity

Sensitivity to light.

photosynthates

Carbohydrate products of photosynthesis.

photosynthesis

(foe tow sin' the sis) [Gk. creating from light] Metabolic processes carried out by green plants and some microorganisms by which visible light is trapped and the energy used to synthesize compounds such as ATP and glucose.

photosynthetic lamellae

The internal membrane system of the cyanobacteria.

photosystem

[Gk. *phos*: light + *systema*: assembly] A light-harvesting complex in the chloroplast thylakoid composed of pigments and proteins. **Photosystem I** absorbs light at 700 nm, passing electrons to ferredoxin and from there to NADPH. **Photosystem II** absorbs light at 680 nm and passes electrons to the electron transport chain in the chloroplast.

photosystem I

See photosystem.

photosystem II

See photosystem.

phototropin

Photoreceptor proteins that mediate light reception in plants.

phototropism

[Gk. *photos*: light + *tropē*: turning] A directed plant growth response to light.

phycoerythrin

A red protein pigment that occurs in red algae.

phylogenetic tree

A graphic representation of these lines of evolutionary descent.

phylogeny

(fy loj' e nee) [Gk. *phylon*: tribe, race + *genesis*: source] The evolutionary history of a particular group of organisms or their genes.

phytoalexins

Substances toxic to pathogens, produced by plants in response to fungal or bacterial infection.

phytochrome

(fy' tow krome) [Gk. *phyton*: plant + *chroma*: color] A plant pigment regulating a large number of developmental and other phenomena in plants. It has two isomers: P_r , which absorbs red light, and P_{fr} , which absorbs far fr red light. P_{fr} is the active form.

phytomers

In plants, the repeating modules that compose a shoot, each consisting of one or more leaves, attached to the stem at a node; an internode; and one or more axillary buds.

phytoremediation

A form of bioremediation that uses plants to clean up environmental pollution.

pie chart

A circular figure that displays proportions of different classes of data in an observed sample.

pigment

A substance that absorbs visible light.

piloting

A form of navigation in which an animal finds its way by remembering landmarks in its environment.

pilus

(plural: pili) A structure that links prokaryote cells at the beginning of conjugation.

pineal gland

Gland located between the cerebral hemispheres that secretes melatonin.

pinocytosis

Endocytosis by a cell of liquid containing dissolved substances.

pioneer species

Species that arrive first to primary successional habitats and must deal with extreme conditions; they tend to have life history strategies that maximize population growth (see *r*-strategists). Also called early succession species.

pistil

[L. *pistillum*: pestle] The structure of an angiosperm flower within which the ovules are borne. May consist of a single carpel, or of several carpels fused into a single structure. Usually differentiated into ovary, style, and stigma.

pith

In plants, relatively unspecialized tissue found within a cylinder of vascular tissue.

pituitary gland

A small gland attached to the base of the brain in vertebrates. Its hormones control the activities of other glands. Also known as the hypophysis.

placenta

(pla sen' ta) The organ in female mammals that provides for the nourishment of the fetus and elimination of the fetal waste products.

plankton

Aquatic organisms that float in the water column, dependent on currents and wind for movement. Plankton include many protists, some algae, and larval animals.

planula

(plan' yew la) [L. *planum*: flat] A free-swimming, ciliated larval form typical of the cnidarians.

plaque

(plack) [Fr. a metal plate or coin] (1) A circular clearing in a layer (lawn) of bacteria growing on the surface of a nutrient agar gel. (2) An accumulation of prokaryotic organisms on tooth enamel. Acids produced by these microorganisms cause tooth decay. (3) A region of arterial wall invaded by fibroblasts and fatty deposits.

plasma cell

An antibody-secreting cell that develops from a B cell; the effector cell of the humoral immune system.

plasmid

A DNA molecule distinct from the chromosome(s); that is, an extrachromosomal element; found in many bacteria. May replicate independently of the chromosome.

plasmodesmata

(singular: plasmodesma) [Gk. *plassein*: to mold + *desmos*: band] Cytoplasmic strands connecting two adjacent plant cells.

plasmogamy

The fusion of the cytoplasm of two cells. (Contrast with karyogamy.)

plate tectonics

[Gk. *tekton*: builder] The scientific study of the structure and movements of Earth's lithospheric plates, which are the cause of continental drift.

platelet

A membrane-bounded body without a nucleus, arising as a fragment of a cell in the bone marrow of mammals. Important to blood-clotting action.

pleiotropy

(plee' a tro pee) [Gk. *pleion*: more] The determination of more than one character by a single gene.

pleural membrane

[Gk. *pleuras*: rib, side] The membrane lining the outside of the lungs and the walls of the thoracic cavity. Inflammation of these membranes is a condition known as pleurisy.

pluripotent

[L. *pluri*: many + *potens*: powerful] Having the ability to form all of the cells in the body. (Contrast with multipotent, totipotent, unipotent.)

pneumatophores

Roots that grow upward out of the water or mud to reach the air and obtain oxygen for the root systems of trees that live in swampy or tidal habitats.

podocytes

Cells of Bowman's capsule of the nephron that cover the capillaries of the glomerulus, forming filtration slits.

poikilotherms

Animals whose body temperatures are largely dependent on environmental temperature.

point mutation

A mutation that results from the gain, loss, or substitution of a single nucleotide. (Contrast with deletion, duplication.)

polar

A molecule with separate and opposite electric charges at two ends, or poles; the water molecule (H₂O) is the most prevalent example. (Contrast with nonpolar.)

polar covalent bond

A covalent bond in which the electrons are drawn to one nucleus more than the other, resulting in an unequal distribution of charge.

polar nuclei

In angiosperms, the two nuclei in the central cell of the megagametophyte; following fertilization they give rise to the endosperm.

polarity

(1) In chemistry, the property of unequal electron sharing in a covalent bond that defines a polar molecule. (2) In development, the difference between one end of an organism or structure and the other.

pole plasm

Cytoplasm at one end of an insect egg that determines that the cells that form at that location will become germ cells.

pollen grain

[L. *pollin*: fine flour] In seed plants, microscopic grains that contain the male gametophyte (microgametophyte) and gamete (microspore).

pollen tube

A structure that develops from a pollen grain through which sperm are released into the megagametophyte.

pollination

The process of transferring pollen from an anther to the stigma of a pistil in an angiosperm or from a strobilus to an ovule in a gymnosperm.

poly A tail

A long sequence of adenine nucleotides (50–250) added after transcription to the 3' end of most eukaryotic mRNAs.

polyandry

Mating system in which one female mates with multiple males. (Contrast with polygyny.)

polyculture

In agriculture, a large scale planting of multiple crop species. (Contrast with monoculture.)

polygyny

Mating system in which one male mates with multiple females. (Contrast with polyandry.)

polymer

[Gk. *poly*: many + *meros*: unit] A large molecule made up of similar or identical subunits called monomers. (Contrast with monomer.)

polymerase chain reaction (PCR)

An enzymatic technique for the rapid production of millions of copies of a particular stretch of DNA where only a small amount of the parent molecule is available.

polymorphic

(pol' lee mor' fik) [Gk. *poly*: many + *morphe*: form, shape] Coexistence in a population of two or more distinct traits.

polyp

(pah' lip) [Gk. *poly*: many + *pous*: foot] In cnidarians, a sessile, asexual life cycle stage.

polypeptide

A large molecule made up of many amino acids joined by peptide linkages. Large polypeptides are called proteins.

polyphyletic

(pol' lee fih leht' ik) [Gk. *poly*: many + *phylon*: tribe] Pertaining to a group that consists of multiple distantly related organisms, and does not include the common ancestor of the group. (Contrast with monophyletic, paraphyletic.)

polyploid

(pol' lee ploid) Possessing more than two entire sets of chromosomes.

polyploidy

(pol' lee ploid ee) The possession of more than two entire sets of chromosomes.

polyribosome (polysome)

A complex consisting of a threadlike molecule of messenger RNA and several (or many) ribosomes. The ribosomes move along the mRNA, synthesizing polypeptide chains as they proceed.

polysaccharide

A macromolecule composed of many monosaccharides (simple sugars). Common examples are cellulose and starch.

pons

[L. *pons*: bridge] Region of the brainstem anterior to the medulla.

population

(1) In biology, any group of organisms coexisting at the same time and in the same place and capable of interbreeding with one another. (2) In statistics, a study group of interest.

population bottleneck

A period during which only a few individuals of a normally large population survive.

population density

The number of individuals in a population per unit of area or volume.

population dynamics

The patterns and processes of change in populations over space and time.

population growth rate

The rate of change in population size over time.

population growth

The change in population size over time.

population size

The total number of individuals in a population.

portal blood vessels

Blood vessels that begin and end in capillary beds.

positional information

In development, the basis of the spatial sense that induces cells to differentiate as appropriate for their location within the developing organism; often comes in the form of a morphogen gradient.

positive cooperativity

Occurs when a molecule can bind several ligands and each one that binds alters the conformation of the molecule so that it can bind the next ligand more easily. The binding of four molecules of O₂ by hemoglobin is an example of positive cooperativity.

positive feedback

In regulatory systems, information that amplifies a regulatory response, increasing the deviation of the system from the set point. (Contrast with negative feedback.)

positive interaction

Trophic or nontrophic interaction between two species in which one or both species benefit and neither is harmed. (See *also* facilitation, mutualism, commensalism.)

positive regulation

A form of gene regulation in which a regulatory macromolecule is needed to turn on the transcription of a structural gene; in its absence, transcription will not occur. (Contrast with negative regulation.)

positive relationship

A relationship in which two variables tend to vary among observations in the same direction.

positive selection

Natural selection that acts to establish a trait that enhances survival in a population. (Contrast with purifying selection.)

postabsorptive state

State in which no food remains in the gut and thus no nutrients are being absorbed. (Contrast with absorptive state.)

posterior

Toward or pertaining to the rear. (Contrast with anterior.)

posterior pituitary

A portion of the pituitary gland derived from neural tissue; involved in the storage and release of antidiuretic hormone and oxytocin.

postzygotic isolating mechanisms

Barriers to the reproductive process that occur after the union of the nuclei of two gametes. (Contrast with prezygotic isolating mechanisms.)

potassium equilibrium potential (E_K)

The negative membrane potential that balances the tendency for K⁺ ions to diffuse out of the cell down its concentration gradient.

potential energy

Energy not doing work but with the potential to do so, such as the energy stored in chemical bonds. (Contrast with kinetic energy.)

power

In reference to statistical tests: refers to the probability of correctly rejecting a null hypothesis when it is false.

P_r

See phytochrome.

pre-motor cortex

The region of the frontal lobe of the cerebrum that is anterior to the primary motor cortex.

pre-mRNA (precursor mRNA)

Initial gene transcript before it is modified to produce functional mRNA. Also known as the primary transcript.

Precambrian

The first and longest period of geological time, during which life originated.

precapillary sphincter

A cuff of smooth muscle that can shut off the blood flow to a capillary bed.

precocial

Born or hatched in a relatively advanced state that allows a high degree of independence from the parents.

predation

A trophic or feeding interaction in which an individual of one species (a predator) kills and/or consumes individuals (or parts of individuals) of another species (its prey).

predator

An organism that kills and/or consumes individuals (or parts of individuals) of another species (its prey).

pressure flow model

An effective model for phloem transport in angiosperms. It holds that sieve element transport is driven by an osmotically generated pressure gradient between source and sink.

pressure potential (Ψ_p)

The hydrostatic pressure of an enclosed solution in excess of the surrounding atmospheric pressure. (Contrast with solute potential, water potential.)

prevailing winds

The circulation of air (wind) that moves across the Earth's surface in a predominately single direction.

prey

[L. *praeda*: booty] An organism killed and/or consumed by a predator as an energy

source.

prezygotic isolating mechanisms

Barriers to the reproductive process that occur before the union of the nuclei of two gametes (Contrast with postzygotic isolating mechanisms.)

primary active transport

Active transport in which ATP is hydrolyzed, yielding the energy required to transport an ion or molecule against its concentration gradient. (Contrast with secondary active transport.)

primary bronchi

The first airways that branch off of the trachea.

primary cell wall

In plant cells, a structure that forms at the middle lamella after cytokinesis, made up of cellulose microfibrils, hemicelluloses, and pectins. (Contrast with secondary cell wall.)

primary consumer

An organism (herbivore) that feeds on primary producers.

primary embryonic organizer

See organizer.

primary endosymbiosis

The engulfment of a cyanobacterium by a larger eukaryotic cell that gave rise to the first photosynthetic eukaryotes with chloroplasts.

primary growth

In plants, growth that is characterized by the lengthening of roots and shoots and by the proliferation of new roots and shoots through branching. (Contrast with secondary growth.)

primary immune response

The first response of the immune system to an antigen, involving recognition by lymphocytes and the production of effector cells and memory cells. (Contrast with secondary immune response.)

primary lysosomes

A lysosome before fusion with an endosome.

primary meristem

Meristem that produces the tissues of the primary plant body.

primary motor cortex

See motor cortex.

primary oocyte

(oh' eh site) [Gk. *oon*: egg + *kytos*: container] The diploid progeny of an oogonium.

In many species, a primary oocyte enters prophase of the first meiotic division, then remains in developmental arrest for a long time before resuming meiosis to form a secondary oocyte and a polar body.

primary producer

A photosynthetic or chemosynthetic organism that synthesizes complex organic molecules from simple inorganic ones.

primary sex determination

Genetic determination of gametic sex, male or female.

primary sex organs

Testes and ovaries.

primary somatosensory cortex

See somatosensory cortex.

primary spermatocyte

The diploid progeny of a spermatogonium; undergoes the first meiotic division to form secondary spermatocytes.

primary structure

The specific sequence of amino acids in a protein.

primary succession

Succession of ecological communities that begins in an area devoid of life, such as on recently exposed glacial till or lava flows. (Contrast with secondary succession.)

primase

(prigh' maze) An enzyme that catalyzes the synthesis of a primer for DNA replication.

primer

Strand of nucleic acid, usually RNA, that is the necessary starting material for the synthesis of a new DNA strand, which is synthesized from the 3' end of the primer.

primitive streak

A midline ridge that forms in the avian blastula that will become the blastopore.

probability

A numerical quantity that expresses the likelihood of an event occurring on a scale from 0 (no chance of the event) to 1 (certainty of the event).

probe

A segment of single-stranded nucleic acid used to identify DNA molecules containing the complementary sequence.

proboscis

An elongated nose or sucking mouthpart that is typically tubular and flexible.

procambium

Primary meristem that produces the vascular tissue.

processive

Pertaining to an enzyme that catalyzes many reactions each time it binds to a substrate, as DNA polymerase does during DNA replication.

production efficiency

The proportion of assimilated biomass used to produce new consumer biomass or net secondary production.

products

The molecules that result from the completion of a chemical reaction.

progesterone

[L. *pro*: favoring + *gestare*: to bear] A female sex hormone that maintains pregnancy.

prokaryotes

Unicellular organisms that do not have nuclei or other membrane-enclosed organelles. Includes Bacteria and Archaea. (Contrast with eukaryotes.)

promoter

A DNA sequence to which RNA polymerase binds to initiate transcription.

proofreading

During DNA replication, a mechanism that excises a base that is incorrectly inserted according to the template (e.g., an A opposite a template G) and inserts the correct base (e.g., C opposite template G).

prop roots

Adventitious roots in some monocots that function as supports for the shoot.

prophage

(pro' fayj) The noninfectious units that are linked with the chromosomes of the host bacteria and multiply with them but do not cause dissolution of the cell. Prophage can later enter into the lytic phase to complete the virus life cycle.

prostaglandin

Any one of a group of specialized lipids with hormone-like functions. It is not clear that they act at any considerable distance from the site of their production.

prostate gland

In male humans, surrounds the urethra at its junction with the vas deferens; supplies an acid-neutralizing fluid to the semen.

proteases

Digestive enzymes that break the bonds between adjacent amino acids in proteins.

proteasome

In the eukaryotic cytoplasm, a huge protein structure that binds to and digests cellular proteins that have been tagged by ubiquitin.

protected areas

An area in which habitat loss or degradation by human activity is restricted or prohibited.

protein

(pro' teen) [Gk. *protos*: first] Long-chain polymer of amino acids with twenty different common side chains. Occurs with its polymer chain extended in fibrous proteins, or coiled into a compact macromolecule in enzymes and other globular proteins. The component amino acids are encoded in the triplets of messenger RNA, and proteins are the products of genes.

protein hormones

Large hormone molecules made up of chains of generally greater than 50 amino acids; encoded by genes and produced by translation.

protein kinase

(kye' nase) An enzyme that catalyzes the addition of a phosphate group from ATP to a target protein.

protein kinase cascade

A series of reactions in response to a molecular signal, in which a series of protein kinases activate one another in sequence, amplifying the signal at each step.

proteoglycan

A glycoprotein containing a protein core with attached long, linear carbohydrate chains.

proteolysis

[protein + Gk. *lysis*: break apart] An enzymatic digestion of a protein or polypeptide.

proteome

The complete set of proteins that can be made by an organism. Because of alternative splicing of pre-mRNA, the number of proteins that can be made is usually much larger than the number of protein-coding genes present in the organism's genome.

prothoracic gland

A gland in insects that secretes the molting hormone ecdysone.

prothoracicotropic hormone (PTTH)

An insect hormone that controls the prothoracic gland.

prothrombin

The inactive form of thrombin, an enzyme involved in blood clotting.

protocells

A self-organized sphere of lipids proposed as a stepping-stone to the origin of life.

protoderm

Primary meristem that gives rise to the plant epidermis.

proton

(pro' ton) [Gk. *protos*: first, before] (1) A subatomic particle with a single positive charge. The number of protons in the nucleus of an atom determine its element. (2) A hydrogen ion, H^+ .

proton pump

An active transport system that uses ATP energy to move hydrogen ions across a membrane, generating an electric potential.

proton-motive force

Force generated across a membrane having two components: a chemical potential (difference in proton concentration) plus an electrical potential due to the electrostatic charge on the proton.

protonephridium

(plural: protonephridia) [Gk. *proto*: before + *nephros*: kidney] The excretory organ of flatworms, made up of a tubule and a flame cell.

provirus

Double-stranded DNA made by a virus that is integrated into the host's chromosome and contains promoters that are recognized by the host cell's transcription apparatus.

proximal convoluted tubule

The initial segment of a renal tubule, closest to the glomerulus. (Compare with distal convoluted tubule.)

proximate causes

The immediate genetic, physiological, neurological, and developmental mechanisms responsible for a behavior or morphology. (Contrast with ultimate causes.)

PRRs

See pattern recognition receptors.

pseudocoelomate

(soo' do see' low mate) [Gk. *pseudes*: false + *koiloma*: cavity] Having a body cavity, called a pseudocoel, consisting of a fluid-filled space in which many of the internal organs are suspended, but which is enclosed by mesoderm only on its outside.

pseudogene

[Gk. *pseudes*: false] A DNA segment that is homologous to a functional gene but is not expressed because of changes to its sequence or changes to its location in the genome.

pseudoplasmodium

An aggregation of myxamoebas that resembles a plasmodium.

PTH

See parathyroid hormone.

pulmonary arteries

In vertebrates, blood vessels that carry blood from the heart to the lungs.

pulmonary circuit

The portion of the circulatory system by which blood is pumped from the heart to the lungs or gills for oxygenation and back to the heart for distribution. (Contrast with systemic circuit.)

pulmonary valve

A one-way valve between the right ventricle of the heart and the pulmonary artery that prevents backflow of blood into the ventricle when it relaxes.

pulmonary veins

Veins that return oxygenated blood from the lungs to the left atrium.

pulp cavity

The space in the interior of the tooth that contains blood vessels, nerves, and dentine-producing cells.

Punnett square

Method of predicting the results of a genetic cross by arranging the gametes of each parent at the edges of a square.

pupil

The opening in the vertebrate eye through which light passes.

purifying selection

The elimination by natural selection of detrimental characters from a population. (Contrast with positive selection.)

purine

(pure' een) One of the two types of nitrogenous bases in nucleic acids. Each of the purines—adenine and guanine—pairs with a specific pyrimidine.

Purkinje fibers

(pur kin' jee) Specialized heart muscle cells that conduct excitation throughout the ventricular muscle.

pyrimidine

(pe rim' a deen) One of the two types of nitrogenous bases in nucleic acids. Each of the pyrimidines—cytosine, thymine, and uracil—pairs with a specific purine.

pyrogen

[Gk. pry, fire] Molecule that produces a rise in body temperature (fever); may be

produced by an invading pathogen or by cells of the immune system in response to infection.

pyruvate

The ionized form of pyruvic acid, a three-carbon acid; the end product of glycolysis and the raw material for the citric acid cycle.

Q

Q_{10}

A value that compares the rate of a biochemical process or reaction over 10°C temperature ranges. A process that is not temperature-sensitive has a Q_{10} of 1; values of 2 or 3 mean the reaction speeds up as temperature increases.

quadrat

A four sided measurement area of any size used to count the individuals within the area.

qualitative

Based on observation of an unmeasured quality of a trait, as in brown vs. blue.

quantitative

Based on numerical values obtained by measurement, as in quantitative data.

quantitative trait loci

A set of genes determining a complex character (trait) that exhibits quantitative variation (variation in amount rather than in kind).

quantitative variables

Variables that are measured by a quantity, as opposed to ones that differ only in a quality. (Contrast with categorical variables.)

quaternary structure

The specific three-dimensional arrangement of protein subunits. (Contrast with primary, secondary, tertiary structure.)

quorum sensing

The use of chemical communication signals to trigger density-linked activities such as biofilm formation in prokaryotes.

R

R group

The distinguishing group of atoms of a particular amino acid; also known as a side chain.

***r*-strategist**

A species whose life history strategy allows for a high intrinsic rate of population increase (r). (Contrast with K -strategist.)

radial cleavage

Embryonic development in which the planes of cell division are parallel and perpendicular to the animal-vegetal axis of the embryo. (Compare to spiral cleavage.)

radial symmetry

The condition in which any two halves of a body are mirror images of each other, providing the cut passes through the center; a cylinder cut lengthwise down its center displays this form of symmetry.

radiation

The transfer of heat from warmer objects to cooler ones via the exchange of infrared radiation. (See *also* electromagnetic radiation, evolutionary radiation.)

radicle

An embryonic root.

radioactive decay

Spontaneous disintegration of a substance with the emission of ionizing radiation.

radioisotope

A radioactive isotope of an element. Examples are carbon-14 (^{14}C) and hydrogen-3, or tritium (^3H).

radiometric dating

A method for determining the age of objects such as fossils and rocks based on the decay rates of radioactive isotopes.

radula

A rasplike structure used for scraping food particles off a surface.

rain shadow

The relatively dry area on the down-wind side of a mountain range.

random dispersion

The spatial arrangement of individuals within a population, characterized by random spatial patterns. (Compare with clumped dispersion, regular (uniform) dispersion.)

range

The largest minus the smallest observed value for a variable in a sample.

rapid eye movement (REM) sleep

A sleep state characterized by vivid dreams, skeletal muscle relaxation, and rapid eye movements. (Contrast with non-REM sleep.)

reactant

A chemical substance that enters into a chemical reaction with another substance.

reaction center

A group of electron transfer proteins that receive energy from light-absorbing pigments and convert it to chemical energy by redox reactions.

realized niche

A species' niche as defined by its interactions with other species. (Contrast with fundamental niche.)

receptive field

The area of visual space that activates a particular cell in the visual system.

receptor potential

The change in the resting potential of a sensory cell when it is stimulated.

receptor protein

A protein that can bind to a specific molecule, or detect a specific stimulus, within the cell or in the cell's external environment.

receptor

See receptor protein, sensor.

receptor-mediated endocytosis

Endocytosis initiated by macromolecular binding to a specific membrane receptor.

recessive

In genetics, an allele that does not determine phenotype in the presence of a dominant allele. (Contrast with dominance.)

recognition sequence

See restriction site.

recombinant chromatid

In meiosis, a chromatid after crossing over that contains part of a sister chromatid, typically having exchanged that part with the sister chromatid.

recombinant DNA

A DNA molecule made in the laboratory that is derived from two or more genetic sources.

recombinant frequency

The proportion of offspring of a genetic cross that have phenotypes different from the parental phenotypes due to crossing over between linked genes during gamete formation.

rectum

The terminal portion of the gut, ending at the anus.

redox reaction

A chemical reaction in which one reactant is oxidized (loses electrons) and the other is reduced (gains electrons). Short for reduction–oxidation reaction.

reduction

Gain of electrons by a chemical reactant. (Contrast with oxidation.)

refractory period

The time interval after an action potential during which another action potential cannot be elicited from an excitable membrane.

regeneration

The development of a complete individual from a fragment of an organism.

regional species pool

All the species that are limited to a geographic region; sometimes called gamma diversity.

regular (uniform) dispersion

The spatial arrangement of individuals within a population, characterized by evenly spaced individuals. (Compare with clumped dispersion, random dispersion.)

regulated specification

Determination of cell fates due to signals mostly received from neighboring cells.

regulative development

A pattern of animal embryonic development in which the fates of the first blastomeres are not absolutely fixed. (Contrast with mosaic development.)

regulatory sequence

A DNA sequence to which the protein product of a regulatory gene binds.

regulatory system

A system that uses feedback information to maintain a physiological function or parameter at an optimal level. (Contrast with controlled system.)

regulatory T cells (Tregs)

The class of T cells that mediates tolerance to self antigens.

reinforcement

The evolution of enhanced reproductive isolation between populations due to natural selection for greater isolation.

releaser

Sensory stimulus that triggers performance of a stereotyped behavior pattern.

renal

[L. *renes*: kidneys] Relating to the kidneys.

renal artery

The main artery supplying the kidney.

renal pyramids

Tissue of the renal medulla that projects into and releases urine into the renal

pelvis which is drained by the ureter.

renal tubule

A structural unit of the kidney that collects filtrate from the blood, reabsorbs specific ions, nutrients, and water and returns them to the blood, and concentrates excess ions and waste products such as urea for excretion from the body.

renal vein

The main vein carrying blood from the kidney.

renin

An enzyme released from the kidneys in response to a drop in the glomerular filtration rate. Together with angiotensin converting enzyme, converts an inactive protein in the blood into angiotensin.

replication

The duplication of genetic material.

replication fork

A point at which a DNA molecule is replicating. The fork forms by the unwinding of the parent molecule.

replicon

A region of DNA replicated from a single origin of replication.

reporter gene

A genetic marker included in recombinant DNA to indicate the presence of the recombinant DNA in a host cell.

repressor

A protein encoded by a regulatory gene that can bind to a promoter and prevent transcription of the associated gene. (Contrast with activator.)

reproductive isolation

Condition in which two divergent populations are no longer exchanging genes. Can lead to speciation.

reproductive signal

In cell biology, the internal or external signal that causes a cell to initiate its mitotic or meiotic cell division cycle.

residual volume (RV)

In tidal ventilation, the dead space that remains in the lungs at the end of exhalation.

residuals

The deviations, along the y-axis from the linear regression line, of individual observations in a bivariate scatter plot.

resistance (*R*) genes

Plant genes that confer resistance to specific strains of pathogens.

resource

Components of the environment such as food, water, light, and space that are required by all species.

resource partitioning

A situation in which species share limiting resources by using them in different ways, thereby allowing them to coexist.

resource-mediated coexistence

A type of coexistence among competitors in which factors such as disturbance, stress, or predation that act on the dominant competitor, allow inferior competitors access to limiting resources.

respiratory chain

The terminal reactions of cellular respiration, in which electrons are passed from NAD or FAD, through a series of intermediate carriers, to molecular oxygen, with the concomitant production of ATP.

respiratory gases

Oxygen (O₂) and carbon dioxide (CO₂); the gases that an animal must exchange between its internal body fluids and the outside medium (air or water).

resting potential

The membrane potential of a living cell at rest. In cells at rest, the interior is negative to the exterior. (Contrast with action potential.)

restoration ecology

The science and practice of restoring damaged or degraded ecosystems by active human intervention.

restriction digestion

An enzymatic reaction in which a molecule of DNA is fully cleaved by a restriction enzyme.

restriction enzyme

Any of a type of enzyme that cleaves double-stranded DNA at specific sites; extensively used in recombinant DNA technology. Also called a restriction endonuclease.

restriction point (R)

The specific time during G₁ of the cell cycle at which the cell becomes committed to undergo the rest of the cell cycle.

restriction site

A specific DNA base sequence that is recognized and acted on by a restriction endonuclease.

reticular-activating system

[L. *reticulum*: net] A central region of the vertebrate brainstem that includes complex fiber tracts conveying neural signals between the forebrain and the spinal cord, with collateral fibers to a variety of nuclei that are involved in autonomic functions, including arousal from sleep.

reticulation

In a phylogenetic tree, a combining of lineages (through hybridization of gene capture, for example).

reticulum

The second of the four chambers of the ruminant stomach. Along with the rumen, it is where food is partially digested with the assistance of gut bacteria.

retina

(rett' in uh) [L. *rete*: net] The light-sensitive layer of cells in the vertebrate or cephalopod eye.

retrovirus

An RNA virus that contains reverse transcriptase. Its RNA serves as a template for cDNA production, and the cDNA is integrated into a chromosome of the host cell.

reverse transcriptase

An enzyme that catalyzes the production of DNA (cDNA), using RNA as a template; essential to the reproduction of retroviruses.

reverse transcription

Production of DNA using an RNA template.

reversible reaction

A chemical transformation that can occur in either direction, so that reactants become products and vice versa.

reversion mutation

A second- or third-round mutation that reverts the DNA to its original sequence or to a new sequence that results in a non-mutant phenotype.

rhizoids

(rye' zoids) [Gk. root] Hairlike extensions of cells in mosses, liverworts, and a few vascular plants that serve the same function as roots and root hairs in vascular plants. The term is also applied to branched, rootlike extensions of some fungi and algae.

rhizome

(rye' zome) An underground stem (as opposed to a root) that runs horizontally beneath the ground.

rhodopsin

A vertebrate visual pigment involved in transducing photons of light into changes in

the membrane potential of certain photoreceptor cells.

ribose

A five-carbon sugar in nucleotides and RNA.

ribosomal RNA (rRNA)

Several species of RNA that are incorporated into the ribosome. Involved in peptide bond formation.

ribosome

A small particle in the cell that is the site of protein synthesis.

ribozyme

An RNA molecule with catalytic activity.

ribulose biphosphate carboxylase/oxygenase

See rubisco.

risk cost

The increased chance of being injured or killed as a result of performing a behavior, compared to resting. (Compare with energetic cost, opportunity cost.)

RNA (ribonucleic acid)

An often single-stranded nucleic acid whose nucleotides use ribose rather than deoxyribose and in which the base uracil replaces thymine found in DNA. Serves as genome from some viruses. (See ribosomal RNA, transfer RNA, messenger RNA, and ribozyme.)

RNA interference (RNAi)

A mechanism for reducing mRNA translation whereby a double-stranded RNA, made by the cell or synthetically, is processed into a small, single-stranded RNA, whose binding to a target mRNA results in the latter's breakdown.

RNA polymerase

An enzyme that catalyzes the formation of RNA from a DNA template.

RNA processing

Modification of RNA primary transcripts, for example splicing out of introns.

RNA splicing

The last stage of RNA processing in eukaryotes, in which the transcripts of introns are excised through the action of small nuclear ribonucleoprotein particles (snRNP).

rod cells

Light-sensitive cells in the vertebrate retina; these sensory receptor cells are sensitive in extremely dim light and are responsible for dim light, black and white vision.

root

The organ responsible for anchoring the plant in the soil, absorbing water and minerals, and producing certain hormones. Some roots are storage organs.

root apical meristem

Undifferentiated tissue at the apex of the root that gives rise to the organs of the root.

root cap

A thimble-shaped mass of cells, produced by the root apical meristem, that protects the meristem; the organ that perceives the gravitational stimulus in root gravitropism.

root hair

A long, thin process from a root epidermal cell that absorbs water and minerals from the soil solution.

root nodule

A swelling on the root of a leguminous plant, such as the soybean, that contains nitrogen-fixing *Rhizobium* bacteria.

root system

The organ system that anchors a plant in place, absorbs water and dissolved minerals, and may store products of photosynthesis from the shoot system.

rotational cleavage

The form of complete cleavage that occurs in mammals. The first cleavage plane is parallel to the animal–vegetal axis and the two second cleavage planes are at right angles to each other.

rough endoplasmic reticulum (RER)

The portion of the endoplasmic reticulum whose outer surface has attached ribosomes. (Contrast with smooth endoplasmic reticulum.)

round window

A flexible membrane at the end of the lower canal of the cochlea in the human ear. (See *also* oval window.)

RT-PCR

A laboratory manipulation of RNA in which the RNA is first incubated with reverse transcriptase (RT) to make cDNA and then the cDNA amplified for analysis by the polymerase chain reaction (PCR).

rubisco

Contraction of ribulose biphosphate carboxylase/oxygenase, the enzyme that combines carbon dioxide or oxygen with ribulose biphosphate to catalyze the first step of photosynthetic carbon fixation or photorespiration, respectively.

Ruffini endings

Slowly adapting stretch receptor in the skin.

rumen

The first of the four chambers of the ruminant stomach. Along with the reticulum, it is where food is partially digested with the assistance of gut bacteria.

ruminant

Herbivorous, cud-chewing mammals such as cows or sheep, characterized by a stomach that consists of four compartments: the rumen, reticulum, omasum, and abomasum.

S**S phase**

In the cell cycle, the stage of interphase during which DNA is replicated. (Contrast with G1 phase, G2 phase.)

salt glands

Glands on the leaves of some halophytic plants that secrete salt, thereby ridding the plants of excess salt.

saltatory conduction

[L. *saltare*: to jump] The rapid conduction of action potentials in myelinated axons; so called because action potentials appear to “jump” between nodes of Ranvier along the axon.

sample

A set of observations made from a population.

saprobe

[Gk. *sapros*: rotten] An organism (usually a bacterium or fungus) that obtains its carbon and energy by absorbing nutrients from dead organic matter. Also called a saprotroph.

sarcomere

(sark' o meer) [Gk. *sark*: flesh + *meros*: unit] The contractile unit of a skeletal muscle.

sarcoplasm

The cytoplasm of a muscle cell.

sarcoplasmic reticulum

The endoplasmic reticulum of a muscle cell.

saturated fatty acid

A fatty acid in which all the bonds between carbon atoms in the hydrocarbon chain are single bonds—that is, all the bonds are saturated with hydrogen atoms. (Contrast with unsaturated fatty acid.)

scatter plot

A figure that displays the values of observations for two variables along perpendicular axes.

scavenger

An animal that eats larger dead organisms but is not typically considered a detritivore.

Schwann cell

A type of glial cell that myelinates axons in the peripheral nervous system.

scion

In horticulture, the bud or stem from one plant that is grafted to a root or root-bearing stem of another plant (the stock).

sclera

The white outer layer of the eyeball continuous with the cornea.

sclereid

One of the principle types of cells in sclerenchyma.

scrotum

In most mammals, a pouch outside the body cavity that contains the testes.

SDP

See short-day plant.

second filial generation

See F_2 .

second law of thermodynamics

The principle that when energy is converted from one form to another, some of that energy becomes unavailable for doing work.

second messenger

A compound, such as cAMP, that is released within a target cell after a hormone (the first messenger) has bound to a surface receptor on a cell; the second messenger triggers further reactions within the cell.

second polar body

In oogenesis, the daughter cell of the second meiotic division that subsequently degenerates. (See *also* ootid.)

secondary active transport

A form of active transport that does not use ATP as an energy source; rather, transport is coupled to ion diffusion down a concentration gradient established by primary active transport.

secondary bronchi

The airways branching off of the primary bronchi.

secondary cell wall

A thick, cellulosic structure internal to the primary cell wall formed in some plant

cells after cell expansion stops. (Contrast with primary cell wall.)

secondary consumer

An organism (carnivore) that feeds on herbivores or primary consumers. (Contrast with primary consumer.)

secondary endosymbiosis

The engulfment of a photosynthetic eukaryote by another eukaryotic cell that gave rise to certain groups of photosynthetic eukaryotes (e.g., euglenids).

secondary growth

In plants, growth that contributes to an increase in girth. (Contrast with primary growth.)

secondary immune response

A rapid and intense response to a second or subsequent exposure to an antigen, initiated by memory cells. (Contrast with primary immune response.)

secondary lysosome

Membrane-enclosed organelle formed by the fusion of a primary lysosome with a phagosome, in which macromolecules taken up by phagocytosis are hydrolyzed into their monomers. (Contrast with lysosome.)

secondary metabolite

A compound synthesized by a plant that is not needed for basic cellular metabolism. Typically has an antiherbivore or antiparasite function.

secondary oocyte

In oogenesis, the daughter cell of the first meiotic division that receives almost all the cytoplasm. (See *also* first polar body.)

secondary production

Source of energy for organisms and ecosystems that is derived from the consumption of organic compounds produced by other organisms.

secondary sex characteristics

Outward expression of sex determination in organs and tissues, such as body hair and stature in humans.

secondary spermatocyte

One of the products of the first meiotic division of a primary spermatocyte.

secondary structure

Of a protein, localized regularities of structure, such as the α helix and the β pleated sheet. (Contrast with primary, tertiary, quaternary structure.)

secondary succession

The reestablishment of a community when most, but not all, organisms have been destroyed. (Contrast with primary succession.)

secretin

(si kreet' in) A peptide hormone secreted by the upper region of the small intestine when acidic chyme is present. Stimulates the pancreatic duct to secrete bicarbonate ions.

sedimentary rock

Rock formed by the accumulation of sediment grains on the bottom of a body of water. Often contain stratified fossils that allow geologists and biologists to date evolutionary events relative to each other.

seed

A fertilized, ripened ovule of a gymnosperm or angiosperm. Consists of the embryo, nutritive tissue, and a seed coat.

seedling

A plant that has just completed the process of germination.

segment polarity genes

In *Drosophila* (fruit fly) development, segmentation genes that determine the boundaries and anterior-posterior organization of individual segments. Part of a developmental cascade that includes maternal effect genes, gap genes, pair rule genes, and Hox genes.

segmentation

Division of an animal body into segments.

segmentation genes

Genes that determine the number and polarity of body segments.

segregation

In genetics, the separation of alleles, or of homologous chromosomes, from each other during meiosis so that each of the haploid daughter nuclei produced contains one or the other member of the pair found in the diploid parent cell, but never both. This principle was articulated by Mendel as his first law.

selectable marker

A gene, such as one encoding resistance to an antibiotic, that can be used to identify (select) cells that contain recombinant DNA from among a large population of untransformed cells.

selective permeability

Allowing certain substances to pass through while other substances are excluded; a characteristic of membranes.

self-incompatability

In plants, the possession of mechanisms that prevent self-fertilization.

semelparity

Reproducing only once in a lifetime. (Contrast with iteroparity.)

semen

(see' men) [L. *semin*: seed] The thick, whitish liquid produced by the male reproductive system in mammals, containing the sperm.

semicircular canals

Three canals in the human inner ear that form part of the vestibular system.

semiconservative replication

The way in which DNA is synthesized. Each of the two partner strands in a double helix acts as a template for a new partner strand. Hence, after replication, each double helix consists of one old and one new strand.

seminal vesicles

Male accessory sex glands that contribute most of the volume of the semen including mucus, fibrinogen, and fructose.

seminiferous tubules

The tubules within the testes within which sperm production occurs.

sensitive period

The life stage during which some particular type of learning must take place, or during which it occurs much more easily than at other times. Typical of song learning among birds. Also known as the critical period.

sensor

Cell that is responsive to a particular type of physical or chemical stimulation.

sensory mechanisms

The means by which internal or external stimuli are converted into neural signals.

sensory organs

Structures that convert types of internal or environmental energy into electrical signals used by the nervous system.

sensory system

A set of organs and tissues for detecting a stimulus; consists of sensory cells, the associated structures, and the neural networks that process the information.

sensory transduction

The transformation of environmental stimuli or information into neural signals.

sepal

(see' pul) [L. *sepalum*: covering] One of the outermost structures of the flower, usually protective in function and enclosing the rest of the flower in the bud stage.

septate

[L. wall] Divided, as by walls or partitions.

septum

(plural: septa) (1) A partition or cross-wall appearing in the hyphae of some fungi.

(2) The bony structure dividing the nasal passages.

sequence alignment

A method of identifying homologous positions in DNA or amino acid sequences by pinpointing the locations of deletions and insertions that have occurred since two (or more) organisms diverged from a common ancestor.

Sertoli cells

Cells in the seminiferous tubules of the testes that nurture the developing sperm.

sessile

(sess' ul) [L. *sedere*: to sit] Permanently attached; not able to move from one place to another. (Contrast with motile.)

set point

In a regulatory system, the threshold sensitivity to the feedback stimulus.

sex chromosome

In organisms with a chromosomal mechanism of sex determination, one of the chromosomes involved in sex determination (in humans and many other animals, these are the X and Y chromosomes).

sex pilus

A thin connection between two bacteria through which genetic material passes during conjugation.

sex-linked

Gene that is carried on a sex chromosome, such as the X chromosome in mammals.

sex-linked inheritance

Pattern of inheritance characteristic of genes located on the sex chromosomes of organisms having a chromosomal mechanism for sex determination.

sexual reproduction

Reproduction involving the union of gametes.

sexual selection

Selection by one sex of characteristics in individuals of the opposite sex. Also, the favoring of characteristics in one sex as a result of competition among individuals of that sex for mates.

Shannon index

The quantitative index most commonly used to describe species diversity that includes measures of both species richness and species evenness.

shoot apical meristem

Undifferentiated tissue at the apex of the shoot that gives rise to the organs of the shoot.

shoot system

In plants, the organ system consisting of the leaves, stem(s), and flowers.

short tandem repeats (STRs)

Short (1–5 base pairs), moderately repetitive sequences of DNA. The number of copies of an STR at a particular location varies between individuals and is inherited.

short-day plant (SDP)

A plant that flowers when nights are longer than a critical length specific for that plant's species. (Compare to long-day plant.)

short-term memory

Information that is maintained in the brain and can be accessed for a short period of time—seconds to minutes. (Contrast with immediate memory, long-term memory.)

side chain

See R group.

sieve tube element

The characteristic cell of the phloem in angiosperms, which contains cytoplasm but relatively few organelles, and whose end walls (**sieve plates**) contain pores that form connections with neighboring cells.

sigma factor

In prokaryotes, a protein that binds to RNA polymerase, allowing the complex to bind to and stimulate the transcription of a specific class of genes (e.g., those involved in sporulation).

signal sequence

The sequence within a protein that directs the protein to a particular organelle.

signal transduction pathway

The series of biochemical steps whereby a stimulus to a cell (such as a hormone or neurotransmitter binding to a receptor) is translated into a response of the cell.

signaling mechanisms

The means of transferring information between cells, organs, or organisms.

significance level

A particular threshold of making a Type I error (incorrectly rejecting a true null hypothesis) in a statistical test, selected a priori by the investigator.

silencer

A gene sequence binding transcription factors that repress transcription. (Contrast with promoter.)

silent mutation

A change in a gene's sequence that has no effect on the amino acid sequence of a protein either because it occurs in noncoding DNA or because it does not change the amino acid specified by the corresponding codon. (Contrast with frame-shift mutation, missense mutation, nonsense mutation.)

silent substitution

See synonymous substitution.

similarity matrix

A matrix used to compare the degree of divergence among pairs of objects. For molecular sequences, constructed by summing the number or percentage of nucleotides or amino acids that are identical in each pair of sequences.

simple diffusion

Diffusion that does not involve a direct input of energy or assistance by carrier proteins.

simple fruit

A fruit that develops from a single carpel in a single flower.

single nucleotide polymorphisms (SNPs)

Inherited variations in a single nucleotide base in DNA that differ between individuals.

single-strand binding protein

In DNA replication, a protein that binds to single strands of DNA after they have been separated from each other, keeping the two strands separate for replication.

sink

In plants, any organ that imports the products of photosynthesis, such as roots, developing fruits, and immature leaves. (Contrast with source.)

sink populations

Populations that receive more immigrants from other populations within a metapopulation than they produce.

sinoatrial node

(sigh' no ay' tree al) [L. *sinus*: curve + *atrium*: chamber] The pacemaker of the mammalian heart.

sinus venosus

The first chamber of the heart of fish that opens into the atrium.

siRNAs (small interfering RNAs)

Short, double-stranded RNA molecules used in RNA interference.

sister chromatid

Each of a pair of newly replicated chromatids.

sister clades

Two clades that are each other's closest relatives.

sister species

Two species that are each other's closest relatives.

skeletal muscle

A type of muscle tissue characterized by multinucleated cells containing highly ordered arrangements of actin and myosin microfilaments. Also called striated muscle. (Contrast with cardiac muscle, smooth muscle.)

skeletal systems

Organ systems that provide rigid supports—**skeletons**—against which muscles can pull to create directed movements. (See *also* endoskeleton, exoskeleton.)

sliding DNA clamp

Protein complex that keeps DNA polymerase bound to DNA during replication.

sliding filament model

Mechanism of muscle contraction based on the formation and breaking of crossbridges between actin and myosin filaments, causing the filaments to slide together.

slow-twitch fibers

Skeletal muscle fibers specialized for sustained aerobic work; contain myoglobin and abundant mitochondria, and are well-supplied with blood vessels. Also called oxidative or red muscle fibers. (Compare to fast-twitch fibers.)

slow-wave sleep

See non-REM sleep.

small interfering RNAs

See siRNAs.

small intestine

The portion of the gut between the stomach and the colon; consists of the duodenum, the jejunum, and the ileum.

smooth endoplasmic reticulum (SER)

Portion of the endoplasmic reticulum that lacks ribosomes and has a tubular appearance. (Contrast with rough endoplasmic reticulum.)

smooth muscle

Muscle tissue consisting of sheets of mononucleated cells innervated by the autonomic nervous system. (Contrast with cardiac muscle, skeletal muscle.)

sodium–potassium (Na^+ – K^+) pump

Antiporter responsible for primary active transport; it pumps sodium ions out of the cell and potassium ions into the cell, both against their concentration gradients. Also called a sodium–potassium ATPase.

soil fertility

The ability of a soil to sustain plant growth, in terms of the soil's concentration of available plant nutrients.

soil solution

The aqueous portion of soil, from which plants take up dissolved mineral nutrients.

soils

The upper layers of Earth's surface that support plant growth.

solute

A substance that is dissolved in a liquid (solvent) to form a solution.

solute potential (Ψ_s)

A property of any solution, resulting from its solute contents; it may be zero or have a negative value. The more negative the solute potential, the greater the tendency of the solution to take up water through a differentially permeable membrane. (Contrast with pressure potential, water potential.)

solution

A liquid (the solvent) and its dissolved solutes.

solvent

Liquid in which a substance (solute) is dissolved to form a solution.

solvent drag

Transport mechanism in which solutes move across a tissue layer through intercellular spaces by a flow of water (solvent).

somatic cell

[Gk. *soma*: body] All the cells of the body that are not specialized for reproduction. (Contrast with germ cell.)

somatic cell gene therapy

Alteration of the human genome sequence in somatic cells for medical benefit. (Contrast with germ line gene therapy.)

somatic mutation

Permanent genetic change in a somatic cell (as opposed to a germ cell, the egg or sperm). These mutations affect the individual only; they are not passed on to offspring. (Contrast with germ line mutation.)

somatosensory cortex

An area of the parietal lobe that receives touch and pressure information from mechanoreceptors throughout the body; neurons in this area are arranged according to the parts of the body with which they communicate.

somatostatin

Peptide hormone made in the hypothalamus that inhibits the release of other

hormones from the pituitary and intestine.

somite

(so' might) One of the segments into which an embryo becomes divided longitudinally, leading to the eventual segmentation of the animal as illustrated by the spinal column, ribs, and associated muscles.

soredia

(singular: soredium) Propagules of lichens consisting of one or a few photosynthetic cells bound by fungal hyphae.

sorus

(plural: sori) A spore-producing structure on the underside of a fern frond.

source

In plants, any organ that exports the products of photosynthesis in excess of its own needs, such as a mature leaf or storage organ. (Contrast with sink.)

source populations

Populations that serve as a net source of individuals to other populations within a metapopulation.

spatial summation

In the production or inhibition of action potentials in a postsynaptic cell, the interaction of depolarizations and hyperpolarizations produced at different sites on the postsynaptic cell. (Contrast with temporal summation.)

spawning

See external fertilization.

speciation

(spee' see ay' shun) The process of splitting one population into two populations that are reproductively isolated from one another. (Contrast with evolution.)

species

(spee' sees) [L. kind] The base unit of taxonomic classification, consisting of an ancestor–descendant group of populations of evolutionarily closely related, similar organisms. The more narrowly defined “biological species” consists of individuals capable of interbreeding with each other but not with members of other species.

species composition

The kinds of species present in a community.

species concepts

The ways that biologists think about the category of species.

species diversity

A measure that combines the number of species (species richness) in a community and their relative abundances compared with one another (species evenness).

species evenness

The relative abundances of species compared to one another.

species richness

The total number of species within an area.

species–area relationship

The relationship between the size of an area and the numbers of species it supports.

specific heat

The amount of energy that must be absorbed by a gram of a substance to raise its temperature by one degree centigrade. By convention, water is assigned a specific heat of one.

sperm

[Gk. *sperma*: seed] The male gamete.

sperm cells

See sperm.

spermatid

One of the products of the second meiotic division of a primary spermatocyte; four haploid spermatids, which remain connected by cytoplasmic bridges, are produced for each primary spermatocyte that enters meiosis.

spermatogonium

(plural: spermatogonia) In animals, the diploid progeny of a germ cell in males.

spherical symmetry

The simplest form of symmetry, in which body parts radiate out from a central point such that an infinite number of planes passing through that central point can divide the organism into similar halves.

sphincter

(sfink' ter) [Gk. *sphinkter*: something that binds tightly] A ring of muscle that can close an orifice, for example, at the anus.

spicule

[L. arrowhead] A hard, calcareous skeletal element typical of sponges.

spinal reflex

The conversion of afferent to efferent information in the spinal cord without participation of the brain.

spindle apparatus

[O.E. *spindle*: a short stick with tapered ends] Array of microtubules emanating from both poles of a dividing cell during mitosis and playing a role in the movement of chromosomes at nuclear division.

spiral cleavage

A form of complete cleavage in which the cleavage planes are at oblique angles to the animal-vegetal axis.

spirillum

Any of various spiral-shaped bacteria.

spleen

Organ that serves as a reservoir for venous blood and eliminates old, damaged red blood cells from the circulation.

spontaneous generation

The idea that under ordinary circumstances, living organisms can form from non-living materials.

spontaneous mutation

A genetic change caused by internal cellular mechanisms, such as an error in DNA replication. (Contrast with induced mutation.)

sporangiophore

A stalked reproductive structure produced by zygosporic fungi that extends from a hypha and bears one or many sporangia.

sporangium

(spor an' gee um) (plural: sporangia) [Gk. *spora*: seed + *angeion*: vessel or reservoir] In plants and fungi, any specialized structure within which one or more spores are formed.

spore

[Gk. *spora*: seed] (1) Any asexual reproductive cell capable of developing into an adult organism without gametic fusion. In plants, haploid spores develop into gametophytes, diploid spores into sporophytes. (2) In prokaryotes, a resistant cell capable of surviving unfavorable periods.

sporophyte

(spor' o fyte) [Gk. *spora*: seed + *phyton*: plant] In plants and protists with alternation of generations, the diploid phase that produces the spores. (Contrast with gametophyte.)

sporulation

The formation of spores, or resting stages.

stability

The resistance of an ecological community to (or recovery from) a disturbance.

stabilizing selection

Selection against the extreme phenotypes in a population, so that the intermediate types are favored. (Contrast with directional selection, disruptive selection.)

stamen

(stay' men) [L. *stamen*: thread] A male (pollen-producing) unit of a flower, usually composed of an anther, which bears the pollen, and a filament, which is a stalk supporting the anther.

standard deviation

A measure of the spread of observations in a sample. See [Appendix B](#) for the mathematical formula.

standard error

A measure of how close a sample statistic (such as the mean) is likely to be to the true population value.

standard error of the mean

A measure of how close a sample mean is likely to be to the true population value. Calculated by dividing the standard deviation of a sample by the square root of the sample size.

standard free energy

The energy associated with a chemical reaction that can be used to do work. The sum of the enthalpy and the product of temperature and entropy.

starch

[O.E. *stearc*: stiff] A polymer of glucose; used by plants to store energy.

Starling's forces

The two opposing forces responsible for water movement across capillary walls: blood pressure, which squeezes water and small solutes out of the capillaries, and osmotic pressure, which pulls water back into the capillaries.

start codon

The mRNA triplet (AUG) that acts as a signal for the beginning of translation at the ribosome. (Contrast with stop codon.)

static life table

A life table that records the survival and reproduction of individuals of different ages during a single time period.

statistic

A numerical quantity calculated from data.

stele

(steel) [Gk. pillar] The central cylinder of vascular tissue in a plant stem.

stem

In plants, the organ that holds leaves and/or flowers and transports and distributes materials among the other organs of the plant.

stem cell

In animals, an undifferentiated cell that is capable of continuous proliferation. A stem cell generates more stem cells and a large clone of differentiated progeny cells. (See *also* embryonic stem cell.)

stereocilia

Fingerlike extensions of hair cell membranes whose bending initiates sound perception. (See hair cell.)

steroid hormones

Steroid molecules that circulate in the blood and effect cells with appropriate receptors. Examples are testosterone and estrogen.

sticky ends

On a piece of two-stranded DNA, short, complementary, one-stranded regions produced by the action of a restriction endonuclease. Sticky ends facilitate the joining of segments of DNA from different sources.

stigma

[L. *stigma*: mark, brand] The part of the pistil at the apex of the style that is receptive to pollen, and on which pollen germinates.

stock

In horticulture, the root or root-bearing stem to which a bud or piece of stem from another plant (the scion) is grafted.

stoma

(plural: stomata) [Gk. *stoma*: mouth, opening] Small opening in the plant epidermis that permits gas exchange; bounded by a pair of guard cells whose osmotic status regulates the size of the opening.

stomach

An organ that physically (and sometimes enzymatically) breaks down food, preparing it for digestion in the midgut.

stomatal crypt

In plants, a sunken cavity below the leaf surface in which a stoma is sheltered from the drying effects of air currents.

stop codon

Any of the three mRNA codons that signal the end of protein translation at the ribosome: UAG, UGA, UAA. (Contrast with start codon.)

STR

See short tandem repeats.

stratigraphy

The study of geological strata.

stratum

(plural: strata) [L. *stratos*: layer] A layer of rock laid down at a particular time in the past.

stress

An abiotic factor that reduces the growth, reproduction, and/or the survival of some individuals. (Contrast with disturbance.)

stretch receptor

A modified muscle cell embedded in the connective tissue of a muscle that acts as a mechanoreceptor in response to stretching of that muscle.

strigolactones

Signaling molecules produced by plant roots that attract the hyphae of mycorrhizal fungi.

strobilus

(plural: strobili) One of several conelike structures in various groups of plants (including club mosses, horsetails, and conifers) associated with the production and dispersal of reproductive products.

stroke

An embolism in an artery in the brain that causes the cells fed by that artery to die. The specific damage, such as memory loss, speech impairment, or paralysis, depends on the location of the blocked artery.

structural gene

A gene that encodes the primary structure of a protein not involved in the regulation of gene expression.

structural isomers

Molecules made up of the same kinds and numbers of atoms, in which the atoms are bonded differently.

structural motif

A three-dimensional structural element that is part of a larger molecule. For example, there are four common motifs in DNA-binding proteins: helix-turn-helix, zinc finger, leucine zipper, and helix-loop-helix.

style

[Gk. *stēle*: pillar or column] In the angiosperm flower, a column of tissue extending from the tip of the ovary, and bearing the stigma or receptive surface for pollen at its apex.

subduction

In plate tectonics, the movement of one lithospheric plate under another.

submucosa

(sub mew koe' sah) The tissue layer just under the epithelial lining of the lumen of the digestive tract.

subsoil

The soil horizon lying below the topsoil and above the parent rock (bedrock); the zone of infiltration and accumulation of materials leached from the topsoil. Also called the B horizon.

substrate

(sub' strayte) (1) The molecule or molecules on which an enzyme exerts catalytic action. (2) The base material on which a sessile organism lives.

succession

The gradual, sequential series of changes in the species composition of an ecological community following a disturbance.

succulence

In plants, possession of fleshy, water-storing leaves or stems; an adaptation to dry environments.

sulci

(singular: sulcus) The valleys between the folds of the cerebral cortex.

superficial cleavage

A variation of incomplete cleavage in which cycles of mitosis occur without cell division, producing a syncytium (a single cell with many nuclei).

superior vena cava

Large vein that returns deoxygenated blood to the right atrium from the upper body.

suprachiasmatic nuclei (SCN)

In mammals, two clusters of neurons just above the optic chiasm that act as the master circadian clock.

surface area-to-volume ratio

For any cell, organism, or geometrical solid, the ratio of surface area to volume; this is an important factor in setting an upper limit on the size a cell or organism can attain.

surface tension

The attractive intermolecular forces at the surface of liquid; an especially important property of water.

surfactant

A substance that decreases the surface tension of a liquid. Lung surfactant, secreted by cells of the alveoli, is mostly phospholipid and decreases the amount of work necessary to inflate the lungs.

survivorship (l_x)

The fraction of individuals that survive from birth to a given life stage or age.

survivorship curve

A plot of the number of individuals surviving through each life stage (survivorship, l_x) for a hypothetical cohort, usually of 1,000 individuals; includes three general curves called type I, II, and III.

suspension feeders

An organism that feeds on organisms much smaller than itself that are suspended in water or air by means of a straining device. Also called filter feeder.

suspensor

In the embryos of seed plants, the stalk of cells that pushes the embryo into the endosperm and is a source of nutrient transport to the embryo.

sustainable

Pertaining to the use and management of ecosystems in such a way that humans benefit over the long term from specific ecosystem goods and services without compromising others.

swim bladder

An organ used primarily to regulate buoyancy in fish.

symbiosis

(sim' bee oh' sis) [Gk. *sym*: together + *bios*: living] The living together of two or more species in a prolonged and intimate relationship.

symbiotic

A relationship in which two or more organisms live in close association with one another.

symmetry

Pertaining to an attribute of an animal body in which at least one plane can divide the body into similar, mirror-image halves. (See bilateral symmetry, radial symmetry.)

sympathetic nervous system

The division of the autonomic nervous system that works in opposition to the parasympathetic nervous system. (Contrast with parasympathetic nervous system.)

sympatric speciation

(sim pat' rik) [Gk. *sym*: same + *patria*: homeland] Speciation due to reproductive isolation without any physical separation of the subpopulation. (Contrast with allopatric speciation.)

symplast

The continuous meshwork of the interiors of living cells in the plant body, resulting from the presence of plasmodesmata. (Contrast with apoplast.)

symporter

A membrane transport protein that carries two substances in the same direction. (Contrast with antiporter, uniporter.)

synapomorphy

A trait that arose in the ancestor of a phylogenetic group and is present (sometimes in modified form) in all of its members, thus helping to delimit and identify that group. Also called a shared derived trait. (Contrast with derived trait.)

synapse

(sin' aps) [Gk. *syn*: together + *haptēin*: to fasten] A specialized type of junction where a neuron meets its target cell (which can be another neuron or some other type of cell) and information in the form of neurotransmitter molecules is exchanged across a synaptic cleft.

synapsis

(sin ap' sis) The highly specific parallel alignment (pairing) of homologous chromosomes during the first division of meiosis.

synaptic cleft

The space between the presynaptic cell and the postsynaptic cell in a chemical synapse.

syncytium

A single cell with many nuclei produced as a result of superficial cleavage.

synonymous (silent) substitution

A change of one nucleotide in a sequence to another when that change does not affect the amino acid specified (i.e., UUA → UUG, both specifying leucine). (Contrast with nonsynonymous substitution, missense substitution, nonsense substitution.)

systematics

The scientific study of the diversity and relationships among organisms.

systemic acquired resistance

A general resistance to many plant pathogens following infection by a single agent.

systemic circuit

Portion of the circulatory system by which oxygenated blood from the lungs or gills is distributed throughout the rest of the body and returned to the heart. (Contrast with pulmonary circuit.)

systems biology

The scientific study of an organism as an integrated and interacting system of genes, proteins, and biochemical reactions.

systole

(sis' tuh lee) [Gk. contraction] Contraction of a chamber of the heart, driving blood forward in the circulatory system. (Contrast with diastole.)

T**T cell**

A type of lymphocyte involved in the cellular immune response. The final stages of its development occur in the thymus gland. (See *also* cytotoxic T cell, T-helper cell. Contrast with B cell.)

T cell receptor

A protein on the surface of a T cell that recognizes the antigenic determinant for which the cell is specific.

T tubules

A system of tubules that runs throughout the cytoplasm of a muscle fiber, through which action potentials spread.

T-helper (T_H) cell

Type of T cell that stimulates events in both the cellular and humoral immune responses by binding to the antigen on an antigen-presenting cell; target of the HIV-I virus, the agent of AIDS. (Contrast with cytotoxic T cells.)

taproot

The largest plant root from which other roots sprout laterally.

taproot system

A root system typical of eudicots consisting of a primary root (taproot) that extends downward by tip growth and outward by initiating lateral roots. (Contrast with fibrous root system.)

taste bud

A structure in the epithelium of the tongue that includes a cluster of chemoreceptors innervated by sensory neurons.

TATA box

An eight-base-pair sequence, found about 25 base pairs before the starting point for transcription in many eukaryotic promoters, that binds a transcription factor and thus helps initiate transcription.

taxon

(plural: taxa) [Gk. *taxis*: put in order] A biological group (typically a species or a clade) that is given a name.

telencephalon

The outer, surrounding structure of the embryonic vertebrate forebrain, which develops into the cerebrum.

telomerase

An enzyme that catalyzes the addition of telomeric sequences lost from chromosomes during DNA replication.

telomeres

(tee' lo merz) [Gk. *telos*: end + *meros*: units, segments] Repeated DNA sequences at the ends of eukaryotic chromosomes.

temperature inversions

Foggy conditions created when cold air is trapped within a warm inversion layer that forms over valleys during warm days.

template

A molecule or surface on which another molecule is synthesized in complementary fashion, as in the replication of DNA.

temporal lobe

One of the four lobes of the cerebral hemisphere; receives and processes auditory and visual information; involved in recognizing, identifying, and naming objects.

temporal summation

In the production or inhibition of action potentials in a postsynaptic cell, the interaction of depolarizations or hyperpolarizations produced by rapidly repeated stimulation of a single point on the postsynaptic cell. (Contrast with spatial summation.)

tendon

A collagen-containing band of tissue that connects a muscle with a bone.

terminal bud

Growing point at the end of a plant stem or branch.

termination

In molecular biology, the end of transcription or translation.

territorial behavior

Aggressive actions engaged in to defend a habitat or resource such that other animals are denied access.

tertiary endosymbiosis

The mechanism by which some eukaryotes acquired the capacity for photosynthesis; for example, a dinoflagellate that apparently lost its chloroplast became photosynthetic by engulfing another protist that had acquired a chloroplast through secondary endosymbiosis.

tertiary structure

In reference to a protein, the relative locations in three-dimensional space of all the atoms in the molecule. The overall shape of a protein. (Contrast with primary, quaternary, secondary, structures.)

test cross

Mating of a dominant-phenotype individual (who may be either heterozygous or homozygous) with a homozygous-recessive individual.

testis

(tes' tis) (plural: testes) [L. *testis*: witness] The male gonad; the organ that produces the male gametes.

tetanus

[Gk. *tetanos*: stretched] (1) A state of sustained maximal muscular contraction caused by rapidly repeated stimulation. (2) In medicine, an often fatal disease (“lockjaw”) caused by the bacterium *Clostridium tetani*.

tetrad

[Gk. *tettares*: four] During prophase I of meiosis, the association of a pair of homologous chromosomes or four chromatids.

thalamus

[Gk. *thalamos*: chamber] A region of the vertebrate forebrain; involved in integration of sensory input.

thallus

The body of a fungus or plant that is not differentiated into stem and leaves and lacks true roots and a vascular system.

thecal cells

Cells of the ovarian follicle of mammals that bound the follicle and secrete the hormone testosterone.

theory

[Gk. *theoria*: analysis of facts] A far-reaching explanation of observed facts that is supported by such a wide body of evidence, with no significant contradictory evidence, that it is scientifically accepted as a factual framework. Examples are Newton’s theory of gravity and Darwin’s theory of evolution. (Contrast with hypothesis.)

theory of island biogeography

A theory proposing that the number of species on an island (or in another geographically defined and isolated area) represents a balance, or equilibrium, between the rate at which species immigrate to the island and the rate at which resident species go extinct.

thermogenin

Also called Uncoupling Protein 1 (UPC1). A protein in the mitochondria of brown fat that uncouples oxidative phosphorylation.

thermoneutral zone

[Gk. *thermos*: temperature] The range of temperatures over which an endotherm does not have to expend extra energy to thermoregulate.

thermoregulatory adaptations

Physiological and behavioral mechanisms for altering the heat content of the body.

thoracic cavity

[Gk. *thorax*: breastplate] The portion of the mammalian body cavity bounded by the ribs, shoulders, and diaphragm. Contains the heart and the lungs.

thoracic duct

The connection between the lymphatic system and the circulatory system.

threshold

The level of depolarization that causes an electrically excitable membrane to fire an action potential.

thrombin

An enzyme involved in blood clotting; cleaves fibrinogen to form fibrin.

thrombus

(throm' bus) [Gk. *thrombos*: clot] A blood clot that forms within a blood vessel and remains attached to the wall of the vessel. (Contrast with embolus.)

thylakoid

(thigh' la koid) [Gk. *thylakos*: sack or pouch] A flattened sac within a chloroplast. Thylakoid membranes contain all of the chlorophyll in a plant, in addition to the electron carriers of photophosphorylation. Thylakoids stack to form grana.

thymine (T)

Nitrogen-containing base found in DNA.

thyroid gland

[Gk. *thyreos*: door-shaped] A two-lobed gland in vertebrates. Produces the hormone thyroxine.

thyroid-stimulating hormone (TSH)

Hormone produced by the anterior pituitary that stimulates the thyroid gland to produce and release thyroxine. Also called thyrotropin.

thyrotropin

Hormone produced by the anterior pituitary that stimulates the thyroid gland to produce and release thyroxine. Also called thyroid-stimulating hormone (TSH).

thyrotropin-releasing hormone (TRH)

Hormone produced by the hypothalamus that stimulates the anterior pituitary to release thyrotropin.

thyroxine

Hormone produced by the thyroid gland; controls many metabolic processes.

tidal

The bidirectional form of ventilation used by all vertebrates except birds; air enters and leaves the lungs by the same route.

tidal volume (TV)

The volume of air inhaled and exhaled by a resting individual. (Contrast with expiratory reserve volume, tidal volume, vital capacity.)

tight junction

A junction between epithelial cells in which there is no gap between adjacent cells.

tissue

A group of similar cells organized into a functional unit; usually integrated with other tissues to form part of an organ.

titin

A protein that holds bundles of myosin filaments in a centered position within the sarcomeres of muscle cells. The largest protein in the human body.

Toll-like receptors (TLRs)

Membrane proteins of macrophages and dendritic cells with extracellular domains that recognize molecules from microbial pathogens.

tonoplast

The membrane of the plant central vacuole.

topography

The shape and surface features of Earth, in the form of mountains, valleys, ocean basins, etc.

topsoil

The uppermost soil horizon; contains most of the organic matter of soil, but may be depleted of most mineral nutrients by leaching. Also called the A horizon.

totipotent

[L. *toto*: whole, entire + *potens*: powerful] Possessing all the genetic information and other capacities necessary to form an entire individual. (Contrast with multipotent, pluripotent, unipotent.)

trachea

(tray' kee ah) [Gk. *trakhoia*: tube] A tube that carries air to the bronchi of the lungs of vertebrates. When plural (**tracheae**), refers to the major airways of insects.

tracheary element

Either of two types of xylem cells—tracheids and vessel elements— that undergo apoptosis before assuming their transport function.

tracheid

(tray' kee id) A type of tracheary element found in the xylem of nearly all vascular plants, characterized by tapering ends and walls that are pitted but not perforated. (Contrast with vessel element.)

trade winds

Prevailing winds that blow from east to west across the tropics.

trade-off

The relationship between the fitness benefits conferred by an adaptation and the fitness costs it imposes. For an adaptation to be favored by natural selection, the

benefits must exceed the costs.

trait

In genetics, a specific form of a character: eye color is a character; brown eyes and blue eyes are traits. (Contrast with character.)

transcription

The synthesis of RNA using one strand of DNA as a template.

transcription factors

Proteins that assemble on a eukaryotic chromosome, allowing RNA polymerase II to perform transcription.

transect

A linear measurement of any length used to count individuals along the stretch of the line.

transfection

Insertion of recombinant DNA into animal cells.

transfer RNA (tRNA)

A family of folded RNA molecules. Each tRNA carries a specific amino acid and anticodon that will pair with the complementary codon in mRNA during translation.

transformation

(1) A mechanism for transfer of genetic information in bacteria in which pure DNA from a bacterium of one genotype is taken in through the cell surface of a bacterium of a different genotype and incorporated into the chromosome of the recipient cell. (2) Insertion of recombinant DNA into a host cell.

transgenic

Containing recombinant DNA incorporated into the genetic material.

transition

In genetics, a mutation such that a purine base is converted to the other purine (e.g., adenine to guanine) or a pyrimidine to the other pyrimidine (e.g., C to T)

transition state

In an enzyme-catalyzed reaction, the reactive condition of the substrate after there has been sufficient input of energy (activation energy) to initiate the reaction.

transition-state intermediate

Unstable molecule in a reaction which is formed during the reaction when reactants change into products.

translation

The synthesis of a protein (polypeptide). Takes place on ribosomes, using the information encoded in messenger RNA.

translocation

(1) In genetics, a rare mutational event that moves a portion of a chromosome to a new location, generally on a nonhomologous chromosome. (2) In vascular plants, movement of solutes in the phloem.

transmembrane domain

A protein region rich in hydrophobic amino acids that spans the phospholipid bilayer.

transmembrane protein

An integral membrane protein that spans the phospholipid bilayer.

transpiration

[L. *spirare*: to breathe] The evaporation of water from plant leaves and stem, driven by heat from the sun, and providing the motive force to raise water (plus mineral nutrients) from the roots.

transposable element (transposon)

A segment of DNA that can move to, or give rise to copies at, another locus on the same or a different chromosome.

transversion

A mutation that changes a purine to a pyrimidine or vice versa.

tree of life

A term that encompasses the evolutionary history of all life, or a graphic representation of that history.

TRH

See thyrotropin-releasing hormone.

tricuspid valve

The right AV valve. So named because it has three leaves.

triglyceride

A simple lipid in which three fatty acids are combined with one molecule of glycerol.

trimesters

The three stages of human pregnancy, approximately 3 months each in length.

tripartite synapse

The idea that a synapse includes not only the pre-and postsynaptic neurons involved but also encompasses many connections with glial cells called astrocytes.

triploblastic

Having a body derived from three embryonic cell layers (ectoderm, mesoderm, and endoderm). (Contrast with diploblastic, monoblastic.)

triploid (3n) cell

A cell containing three sets of an organism's chromosomes.

trisomic

Containing three rather than two members of a chromosome pair.

trochophore

(troke' o fore) [Gk. *trochos*: wheel + *phoreus*: bearer] A radially symmetrical larval form typical of annelids and mollusks, distinguished by a wheel-like band of cilia around the middle.

trophic

[Gk. *trophes*: nourishment] The feeding relationship between two or more species.

trophic cascade

A series of trophic interactions within a food web in which the rate of consumption at one trophic level results in the change in species abundance or composition at lower trophic levels.

trophic efficiency

A measure of the amount of energy or biomass at one trophic level divided by the amount of energy at the trophic level immediately below it.

trophic level

A subdivision of a food web that includes species that have similar ways of interacting and obtaining energy.

trophoblast

[Gk *trophes*: nourishment + *blastos*: sprout] At the 32-cell stage of mammalian development, the outer group of cells that will become part of the placenta and thus nourish the growing embryo. (Contrast with inner cell mass.)

tropic hormones

Hormones produced by the anterior pituitary that control the secretion of hormones by other endocrine glands.

tropomyosin

[troe poe my' oh sin] One of the three protein components of an actin filament; controls the interactions of actin and myosin necessary for muscle contraction.

troponin

One of the three components of an actin filament; binds to actin, tropomyosin, and Ca^{2+} .

trypsin

A protein-digesting enzyme. Secreted by the pancreas in its inactive form (trypsinogen), it becomes active in the duodenum of the small intestine.

TSH

See thyroid-stimulating hormone.

tube feet

A unique feature of echinoderms; extensions of the water vascular system, which functions in gas exchange, locomotion, and feeding.

tubulin

A protein that polymerizes to form microtubules.

tumor

[L. *tumor*: a swollen mass] A disorganized mass of cells. Malignant tumors spread to other parts of the body.

tumor necrosis factor

A family of cytokines (growth factors) that causes cell death and is involved in inflammation.

tumor suppressor

A gene that codes for a protein product that inhibits cell proliferation; inactive in cancer cells. (Contrast with oncogene.)

turgid

Swollen or distended. In plants, a cell is turgid when its water potential is lower than that of the surrounding environment.

turgor pressure

[L. *turgidus*: swollen] The force exerted by a plant cell against the cell wall when it has taken up water by osmosis. (See pressure potential.)

twitch

A muscle fiber's minimum unit of contraction, stimulated by a single action potential.

tympanic membrane

[Gk. *tympanum*: drum] The eardrum.

Type I error

The incorrect rejection of a true null hypothesis.

type I survivorship curve

A survivorship curve in which individuals experience high overall survivorship through adulthood but a steep decline late in life. (Compare with type II survivorship curve, type III survivorship curve.)

Type II error

The incorrect acceptance of a false null hypothesis.

type II survivorship curves

A survivorship curve in which individuals experience a constant chance of surviving at all ages. (Compare with type I survivorship curve, type III survivorship curve.)

type III survivorship curve

A survivorship curve in which individuals experience low survivorship early in life

and higher survivorship once they reach maturity. (Compare with type I survivorship curve, type II survivorship curve.)

U

ubiquitin

A small protein that is covalently linked to other cellular proteins identified for breakdown by the proteosome.

ultimate causes

In ethology, the evolutionary processes that produce an animal's capacity and tendency to behave in particular ways. (Contrast with proximate causes.)

uncompetitive inhibitor

An enzyme inhibitor that binds to the enzyme-substrate complex.

undershoot

See after-hyperpolarization.

unequal crossing over

When a highly repeated gene sequence becomes displaced in alignment during meiotic crossing over, so that one chromosome receives many copies of the sequence while the second chromosome receives fewer copies. One of the mechanisms of concerted evolution. (See *also* biased gene conversion.)

uniporter

[L. *unus*: one + *portal*: doorway] A membrane transport protein that carries a single substance in one direction. (Contrast with antiporter, symporter.)

unipotent

An undifferentiated cell that is capable of becoming only one type of mature cell. (Contrast with totipotent, multipotent, pluripotent.)

unloading

In phloem, the process of transferring sugars and other molecules in phloem to adjacent plant tissues.

unsaturated fatty acid

A fatty acid whose hydrocarbon chain contains one or more double bonds. (Contrast with saturated fatty acid.)

upper critical temperature

The environmental temperature at which a resting endotherm must actively increase its heat loss to avoid a rise in its body temperature.

upwelling

A process by which offshore winds in combination with the Coriolis effect push warmer surface water away from the shore, allowing cold, nutrient-rich water from deeper waters to rise to the surface.

uracil (U)

A pyrimidine base found in nucleotides of RNA.

urea

(you ree' uh) A compound that is the main form of nitrogen excreted by many animals, including mammals. (Compare with ammonia, uric acid.)

ureotelic

Pertaining to an organism in which the final product of the breakdown of nitrogen-containing compounds (primarily proteins) is urea. (Contrast with ammonotelic, uricotelic.)

ureter

(your' uh tur) Long duct leading from the vertebrate kidney to the urinary bladder or the cloaca.

urethra

(you ree' thra) In most mammals, the canal through which urine is discharged from the bladder and which serves as the genital duct in males.

uric acid

A compound that serves as the main excreted form of nitrogen in some animals, particularly those which must conserve water, such as birds, insects, and reptiles. (Compare with ammonia, urea.)

uricotelic

Pertaining to an organism in which the final product of the breakdown of nitrogen-containing compounds (primarily proteins) is uric acid. (Contrast with ammonotelic, ureotelic.)

urinary bladder

A structure in which urine is stored until it can be excreted to the outside of the body.

urine

(you' rin) In vertebrates, the fluid waste product containing the toxic nitrogenous by-products of protein and nucleic acid metabolism.

uterine cycle

In human females, the monthly cycle of events by which the endometrium is prepared for the arrival of a blastocyst. (Contrast with ovarian cycle).

uterus

(yoo' ter us) [L. *utero*: womb] A specialized portion of the female reproductive tract in mammals that receives the fertilized egg and nurtures the embryo in its early development. Also called the womb.

V**vaccination**

Injection of virus or bacteria or their proteins into the body, to induce immunity. The injected material is usually attenuated (weakened) before injection and is called a vaccine.

vacuole

(vac' yew ole) Membrane-enclosed organelle in plant cells that can function for storage, water concentration for turgor, or hydrolysis of stored macromolecules.

vagina

(vuh jine' uh) [L. sheath] In female animals, the entry to the reproductive tract.

valence shell

The outermost energy shell of an atom, containing the valence electrons involved in chemical reactivity.

van der Waals forces

Weak attractions between atoms resulting from the interaction of the electrons of one atom with the nucleus of another. This type of attraction is about one-fourth as strong as a hydrogen bond.

variable region

The portion of an immunoglobulin molecule or T cell receptor that includes the antigen-binding site and is responsible for its specificity. (Contrast with constant region.)

vas deferens

(plural: vasa deferentia) Duct that transfers sperm from the epididymis to the urethra.

vasa recta

Blood vessels that parallel the loops of Henle and the collecting ducts in the renal medulla of the kidney.

vascular bundle

In vascular plants, a strand of vascular tissue, including xylem and phloem as well as thick-walled fibers.

vascular cambium

(kam' bee um) [L. *cambiare*: to exchange] In plants, a lateral meristem that gives rise to secondary xylem and phloem.

vascular tissue system

The transport system of a vascular plant, consisting primarily of xylem and phloem. (Contrast with dermal tissue system, ground tissue system.)

vasopressin

A hormone that promotes water reabsorption by the kidney. Produced by neurons in the hypothalamus and released from nerve terminals in the posterior pituitary. Also called antidiuretic hormone or ADH.

vector

- (1) An agent, such as an insect, that carries a pathogen affecting another species.
- (2) A plasmid or virus that carries an inserted piece of DNA into a bacterium for cloning purposes in recombinant DNA technology.

vegetal hemisphere

The lower portion of some animal eggs, zygotes, and embryos, in which the dense nutrient yolk settles. The vegetal pole is to the very bottom of the egg or embryo. (Contrast with animal hemisphere.)

vegetal pole

The point at the end of the developing egg where yolk is most concentrated.

vegetative

Nonreproductive, nonflowering, or asexual.

vegetative meristem

An apical meristem that produces leaves.

vegetative reproduction

Asexual reproduction through the modification of stems, leaves, or roots.

vein

[L. *vena*: channel] A blood vessel that returns blood to the heart. (Contrast with artery.)

ventral

[L. *venter*: belly, womb] Toward or pertaining to the belly or lower side. (Contrast with dorsal.)

ventricle

A muscular heart chamber that pumps blood through the lungs or through the body.

venule

A small blood vessel draining a capillary bed that joins others of its kind to form a vein. (Contrast with arteriole.)

vernalization

[L. *vernalis*: spring] Events occurring during a required chilling period, leading eventually to flowering.

vertebral column

[L. *vertere*: to turn] The jointed, dorsal column that is the primary support structure of vertebrates.

very low-density lipoproteins (VLDLs)

Lipoproteins that consist mainly of triglyceride fats, which they transport to fat cells in adipose tissues throughout the body; associated with excessive fat deposition

and high risk for cardiovascular disease.

vessel element

A type of tracheary element with perforated end walls; found only in angiosperms. (Contrast with tracheid.)

vestibular system

(ves tib' yew lar) [L. *vestibulum*: an enclosed passage] Structures within the inner ear that sense changes in position or momentum of the head, affecting balance and motor skills.

vestibule

A central part of the inner ear involved in balance.

vicariance

(vye care' ee uns) [L. *vicus*: change] The evolutionary separation of species due to a barrier that results in the geographic isolation of species that once were connected to one another.

villi

(vil' lus) (singular: villus) [L. *villus*: shaggy hair or beard] Hairlike projections from a membrane; for example, from many gut walls.

virion

(veer' e on) The virus particle, the minimum unit capable of infecting a cell.

virus

Any of a group of ultramicroscopic particles constructed of nucleic acid and protein (and, sometimes, lipid) that require living cells in order to reproduce. Viruses evolved multiple times from different cellular species.

visceral mass

The bulk of the digestive, reproductive, excretory, and respiratory systems of mollusks, contained within the shell.

vital capacity (VC)

The maximum capacity for air exchange in one breath; the sum of the tidal volume and the inspiratory and expiratory reserve volumes.

vitamin

[L. *vita*: life] An organic compound that an organism cannot synthesize, but nevertheless requires in small quantities for normal growth and metabolism.

vitelline envelope

The inner, proteinaceous protective layer of a sea urchin egg.

viviparity

(vye vi par' uh tee) Reproduction in which fertilization of the egg and development of the embryo occur inside the mother's body. (Contrast with oviparity.)

vivipary

Premature germination in plants.

voltage

A measure of the difference in electrical charge between two points.

voltage-gated channel

A type of gated channel that opens or closes when a certain voltage exists across the membrane in which it is inserted.

vomeronasal organ (VNO)

Chemosensory structure embedded in the nasal epithelium of amphibians, reptiles, and many mammals. Often specialized for detecting pheromones.

W**waggle dance**

A behavior of honeybees that communicates the direction and distance to a food source or a location for a new colony.

Walter climate diagram

A graphic technique that plots temperature and precipitation data to visualize a growing season for plants (those months when average temperatures are above freezing and average precipitation is sufficient for plant growth).

warning signal

A visual or acoustical defense mechanism used by prey species to advertise to predators that they may be toxic.

water potential (Ψ , psi)

In osmosis, the tendency for a system (a cell or solution) to take up water from pure water through a differentially permeable membrane.

water vascular system

In echinoderms, a network of water-filled canals that functions in gas exchange, locomotion, and feeding.

wavelength

The distance between successive peaks of a wave train, such as electromagnetic radiation.

weather

The short-term state of atmospheric conditions (temperature, precipitation, humidity, wind direction and velocity) at a particular place and time. (Contrast with climate.)

weathered

The mechanical and chemical processes by which rocks are broken down into soil particles.

Wernicke's area

A region in the temporal lobe of the human brain that is involved with the sensory aspects of language.

westerlies

Prevailing winds that blow from west to east across the mid-latitudes. (Compare with easterlies.)

white blood cells

Cells in the blood plasma that play defensive roles in the immune system. Also called leukocytes.

white matter

In the central nervous system, tissue that is rich in axons. (Contrast with gray matter.)

wild type

Geneticists' term for standard or reference type. Deviants from this standard, even if the deviants are found in the wild, are usually referred to as mutant. (Note that this terminology is not usually applied to human genes.)

wood

Secondary xylem tissue.

X**xerophyte**

(zee' row fyte) [Gk. *xerox*: dry + *phyton*: plant] A plant adapted to an environment with limited water supply.

xylem

(zy' lum) [Gk. *xylon*: wood] In vascular plants, the tissue that conducts water and minerals; xylem consists, in various plants, of tracheids, vessel elements, fibers, and other highly specialized cells.

xylem sap

The liquid contents of the xylem.

xylem vessels

Continuous tubes that conduct water in plants.

Y**yeasts**

Microscopic fungi consisting of single oval cells that reproduce by budding.

yolk

[M.E. *yolke*: yellow] The stored food material in animal eggs, rich in protein and lipids.

yolk sac

In reptiles, birds, and mammals, the extraembryonic membrane that forms from the endoderm of the hypoblast; it encloses and digests the yolk.

Z

zeatin

A cytokinin originally purified from corn kernels.

zeaxanthin

A blue-light receptor involved in the opening of plant stomata.

zona pellucida

A jellylike substance that surrounds the mammalian ovum when it is released from the ovary.

zone of cell division

The apical and primary meristems of a plant root; the source of all cells of the root's primary tissues.

zone of cell elongation

The part of a plant root, generally above the zone of cell division, where cells are expanding (growing), primarily in the longitudinal direction.

zone of maturation

The part of a plant root, generally above the zone of cell elongation, where cells are differentiating.

zygospore

Multinucleate, diploid cell that is a resting stage in the life cycle of zygosporic fungi.

zygote

(zye' gote) [Gk. *zygotos*: yoked] The cell created by the union of two gametes, in which the gamete nuclei are also fused. The earliest stage of the diploid generation.

zymogen

The inactive precursor of a digestive enzyme; secreted into the lumen of the gut, where a protease cleaves it to form the active enzyme.

taxol, [609](#), [610](#)

Cancers

cancer cells compared to normal cells, [235](#)
detecting with DNA microarrays, [390](#), [391](#)
DNA methylation and, [350](#)
DNA testing, [334](#)
effects of electromagnetism on cancer cells, [266](#)
epigenetic changes and, [356](#)
future research directions, [237](#)
genome sequencing, [378](#)
HeLa cells, [213](#)
a multifactorial disease, [321–322](#)
prevalence, [234](#)
ras signaling cascade, [138](#), [139](#), [144](#), [147](#)
retroviruses, [548](#)
skin cancer, [107](#)
somatic mutations, [321](#)
telomerase, [281](#)
unregulated cell growth, [235–236](#)
virus hijacking of cyclin degradation, [355](#)

Candida albicans, [617](#)

Candida krusei, [490–491](#)

Cane toad (*Rhinella marina*), [1183](#)

Canines, [1075](#), [1076](#)

Canis lupus familiaris. See [Dogs](#)

Canis simensis (Ethiopian wolf), [1266](#)

Capacitance vessels, [1061](#)

Capillaries and capillary beds

autoregulation of blood flow, [1063](#)
blood–brain barrier, [1061](#)
perfusing the lungs, [1032](#)
peritubular, [1100](#), [1101](#), [1102](#), [1103](#)
structure and function, [1059–1060](#)

Capillary action hypothesis, of xylem water transport, [740](#)

Capsid, [346](#)

Capsule, [86](#), [87](#)

Captive breeding, [1264–1265](#), [1267](#)

Carapace, [676](#), [677](#)

Carbo-loading, [1013](#)

Carbohydrases, [1077](#)

Carbohydrates

breakdown by digestive enzymes, [1077](#)
categories of, [54](#)
energy stores in the animal body, [1070](#)
food energy for animals, [1069–1070](#)
functional groups, [57–58](#)
functions, [54](#)
general formula, [54](#)
glycosidic linkages, [55–56](#)
membrane-associated, [112](#), [114–115](#), [116](#)
monosaccharides, [54–55](#)
polysaccharides, [56–57](#)
product of photosynthesis, [194](#), [196](#)
properties and characteristics as macromolecules, [42–45](#)
structure, [42](#)
transport by phloem, [744–747](#)

Carbon

carbon skeletons in biosynthesis, [1071–1072](#)
covalent bonds, [29](#), [30](#)
electronegativity, [30](#)
global carbon cycle, [616](#), [1230–1231](#), [1238–1240](#)
isomers, [43](#)

isotopes and isotope analyses, [24](#), [25–26](#)
light-independent reactions in photosynthesis, [196](#), [200](#)

Carbon-14, [509](#)

Carbon dioxide

alternative electron transporter in anaerobic microbes, [185](#)
in the atmosphere (see [Atmospheric carbon dioxide](#))
bicarbonate buffer system, [1107](#), [1108](#)
blood transport, [1037–1038](#)
in bread dough and beer, [629](#)
 C_4 metabolism, [208](#)
carbon-fixation reactions in photosynthesis (see [Carbon-fixation reactions](#))
chemical evolution and the origin of life, [73](#)
a greenhouse gas, [193](#)
partial pressure, [1025](#), [1038](#)
in photorespiration, [206](#)
product of fermentation, [185](#), [186](#)
product of the citric acid cycle, [178](#)
in the regulation of breathing, [1039–1040](#)
a respiratory gas, [1023](#)
respiratory gas exchange, [1025](#)
stomatal opening controls plant uptake of, [743–744](#)
See also [Atmospheric carbon dioxide](#)

Carbon fixation, chemoautotrophs, [545](#)

Carbon-fixation reactions

atmospheric carbon dioxide levels and, [208](#)
 C_3 and C_4 plants, [207–208](#)
Calvin cycle process, [202–205](#)
CAM plants, [208](#)
chemical equation, [194](#)
elucidation of steps in, [202–203](#)
energy requirement, [200](#)
evolution, [208](#)
interaction with other metabolic pathways, [209](#)
as light-independent reactions, [196](#)
rubisco and photorespiration, [205–206](#)
See also [Calvin cycle](#)

Carbon monoxide, [1036](#)

Carbon skeletons, [1071–1072](#)

Carbonate ions, [1238](#)

Carbonic acid

from bicarbonate, [37](#)
bicarbonate buffer system, [38](#), [1107](#), [1108](#)
in cation exchange, [755](#)
in ocean acidification, [1240](#)
in soil formation, [755](#)

Carbonic anhydrase

bicarbonate buffer system, [1107](#), [1108](#)
in blood transport of carbon dioxide, [1038](#)
in pancreas secretion of bicarbonate ions, [1083](#)
in parietal cell generation of H^+ gradients, [1081](#), [1082](#)

Carboniferous period

atmospheric oxygen levels, [507](#), [515](#)

modulation by DNA technology, [388](#)
overview, [6–7](#)
proteins as the major products of, [289–291](#)
transcription differences between eukaryotes and prokaryotes, [298–300](#)
transcription of DNA to produce RNA, [293–298](#)

Gene families

concerted evolution, [498–500](#)
defined, [371](#)
homologous genes, [501](#)
origin through gene duplication, [498](#), [499](#)

Gene flow, effect on allele frequencies, [432](#)

Gene-for-gene concept, [810](#)

“Gene guns,” [383](#)

Gene knockouts, [389–390](#), [1119](#)

Gene pool, [428](#), [434](#)

Gene regulation

by auxin and gibberellins, [776](#)
effects of maternal stress on, [336](#)
epigenetic, [349–353](#)
prokaryotes, [337–341](#)
RNA splicing, [353](#), [354](#)
small RNAs, [353–354](#)
transcription factors in eukaryotes, [342–345](#)
viruses, [345–348](#)

Gene regulatory proteins, [46](#)

Gene silencing, [354](#)

Gene therapy, [332–333](#)

Gene trees, [498](#), [499](#), [500–501](#), [532](#), [533](#)

General immunity, in plants, [807–811](#)

General transcription factors, [342–343](#)

Generalist herbivores, [1192](#)

Generation time, [1177](#)

Generative cell, [789](#), [790](#), [791](#)

Genes

alleles, [244](#) (see also [Alleles](#))
animal behavior and, [1118–1120](#)
artificial life, [366–367](#)
biological information and the genetic code, [5–7](#)
coding for protein, [289–291](#)
CRISPR technology, [388–389](#)
defined, [5](#), [6](#), [68–69](#), [242](#)
DNA testing, [330–331](#)
evolution (see [Gene evolution](#);
Molecular evolution)
gene–environment interactions, future research directions, [264](#)
genetic linkage, [255–261](#)

- homologous, [416–417](#)
- information flow to proteins, [292–293](#)
- interactions to produce phenotype, [253–255](#)

Ionic attractions

description of, [31](#), [32](#)

protein structure, [48](#), [49–50](#), [51](#), [52](#)

Ionic concentrations, regulation by excretory systems, [1094–1096](#)

Ionizing radiation, [318](#)

Ions

absorption in the large intestine, [1084](#)

defined, [31](#)

effect on stomatal opening, [743–744](#)

electric current and, [942](#)

ionic attractions, [31](#), [32](#)

plant uptake and transport, [737–738](#), [753](#)

in xylem and phloem fluids, [739](#)

IP₃–DAG pathway, [142](#)

Ipomoea batatas (sweet potato), [726](#), [1223](#)

Iridium, [514](#)

Iris (eye), [973](#), [974](#)

Iris (plant), [800](#)

Irisin

“browning” of white fat by, [844](#)

future research areas, [864](#)

mediation of the effects of exercise on glucose metabolism, [861–862](#), [864](#)

mediation of the effects of exercise on the brain, [852](#), [853](#), [864](#)

Iron

alternative electron transporter in anaerobic microbes, [185](#)

animal nutrition, [1072](#), [1073](#)

ferritin synthesis, [355](#)

plant nutrition, [751](#), [752](#)

primary production in aquatic systems and, [1232](#)
role in catalyzed reactions, [162](#)
Iron deficiency, [1073](#)
Iron oxide, [514](#)
Irreversible inhibition, [163–164](#), [165](#)
Ischium, [1015](#)
Islands. See [Theory of island biogeography](#)

- binding of ligands to, [134–135](#)
- classification by location and function, [135–137](#)
- function, [46](#)
- in intercellular signaling, [131](#)
- of neurotransmitters, [952–954](#)
- in receptor-mediated endocytosis, [126–127](#)
- sensory (see [Sensors](#))

- in sensory transduction, [961–962](#)
- signal transduction pathways, [133](#)
- specificity, [133](#)
- Recessive genes, [245](#)
- Recessive traits
 - defined, [242](#)
 - red hair in humans, [240](#), [248](#), [249](#), [264](#)
- Recognition sequence (recognition site), [323–324](#), [341](#)
- Recombinant chromatids, [227](#), [230](#)
- Recombinant DNA technology
 - cutting and rejoining of DNA, [381–382](#)
 - defined, [381](#)
 - DNA microarrays, [390–391](#)
 - future research directions, [397](#)
 - gene inactivation or editing with CRISPR, [388–389](#)
 - gene knockout with complementary RNA, [389–390](#)
 - inserting DNA into cells, [382–386](#)
 - modulation of gene expression, [388](#)
 - production of tissue plasminogen activator, [380](#), [397](#)
 - selectable marker genes, [383](#), [384–385](#)
 - sources of DNA, [386–388](#)
- Recombinant frequencies, [257–258](#)
- Rectal salt glands, [1100](#)
- Rectum, [1076](#), [1079](#), [1084](#)
- Red algae, [199](#), [555](#), [573](#), [574–575](#)
- Red-and-green macaw (*Ara chloropterus*), [1127](#)
- Red blood cells (RBCs)
 - 2,3-bisphosphoglycerate, [1036–1037](#)
 - carbonic anhydrase, [1038](#)
 - functions, [826](#)
 - growth factors, [219](#)
 - hematocrit, [1034](#), [1057](#)
 - oligosaccharides and ABO blood types, [252](#)
 - production in bone marrow, [1034–1035](#), [1058](#)
 - production of hemoglobin, [1058](#)
 - removal by the spleen, [1058](#)
 - sickle-cell disease, [314](#), [320](#)
 - transport of respiratory gases, [1034–1037](#), [1057–1058](#)
- Red cotton bug, [680](#)
- Red cups, [627](#)
- Red deer (*Cervus elaphus*), [844](#)
- Red fluorescent proteins, [448](#), [464](#)
- Red fox (*Vulpes vulpes*), [1261](#)
- Red-green color blindness, [260](#)
- Red hair, inheritance in humans, [240](#), [248](#), [249](#), [264](#)
- Red-legged frog (*Rana aurora*), [1001](#)
- Red light
 - flowering and, [795](#), [796](#)
 - plant phytochromes and, [780–782](#)
- Red mangroves, [1263](#)
- Red muscle, [1010](#)
- Red tides, [552](#), [567](#)
- Red wine, [107](#)
- Red-winged blackbirds, [1134](#), [1135](#)
- Redi, Francesco, [70–71](#)
- Redox reactions. See [Oxidation–reduction reactions](#)
- Reduction, [174](#)

Reviewers and Contributors	40
Media and Supplements	49
Contents	53
Part One The Science of Life and Its Chemical Basis	107
1 Studying Life	108
Investigatinglife Corals in Hot Water	108
1.1 Living Organisms Share Similarities and a Common Origin	110
Life arose from non-life via chemical evolution	114
Cellular structure evolved in the common ancestor of life	116
Photosynthesis allows some organisms to capture energy from the sun	120
Biological information is stored in a genetic code common to all organisms	122
Populations of all living organisms evolve	125
Biologists trace the evolutionary tree of life	129
Cellular differentiation and specialization underlie multicellular life	131
Organisms extract energy and raw materials from the environment	132
Living organisms must regulate their internal environment	134
Living organisms interact	134
1.2 Biologists Investigate Life through Experiments That Test Hypotheses	137
Observing and quantifying are important skills	137
Scientific methods combine observation, experimentation, and logic	137
Good experiments have the potential to falsify hypotheses	140
Statistical methods are essential scientific tools	140
Investigatinglife Corals in Hot Water	141
Experiment	141
Work with the data	143
Discoveries in biology can be generalized	145
Not all forms of inquiry are scientific	145
1.3 Understanding Biology Is Important for Health, Well-Being, and Public-	

Policy Decisions	147
Modern agriculture depends on biology	147
Biology is the basis of medical practice	148
Biology can inform public policy	149
Biology is crucial for understanding ecosystems	151
Biodiversity helps us understand, enjoy, and appreciate our world	152
Apply What You've Learned	159
2 Small Molecules and the Chemistry of Life	161
Investigatinglife Tracking a Dinosaur	162
2.1 Atomic Structure Explains the Properties of Matter	163
What are atoms?	163
An element consists of only one kind of atom	164
Each element has a unique number of protons	165
The number of neutrons differs among isotopes	166
Investigatinglife Determining Beef Source in Big Macs Using Isotope Analysis	168
Experiment	168
Work with the data	168
The behavior of electrons determines chemical bonding and geometry	170
2.2 Atoms Bond to Form Molecules	173
Covalent bonds consist of shared pairs of electrons	174
Ionic attractions form by electrical attraction	179
Hydrogen bonds may form within or between molecules with polar covalent bonds	182
Hydrophobic interactions bring together nonpolar molecules	183
Van der Waals forces involve contacts between atoms	185
2.3 Atoms Change Partners in Chemical Reactions	187
2.4 Water Is Critical for Life	190
Water has a unique structure and special properties	190
The reactions of life take place in aqueous solutions	193
Aqueous solutions may be acidic or basic	195
Apply What You've Learned	206
3 Proteins, Carbohydrates, and Lipids	208
Investigatinglife Weaving a Web	209
3.1 Macromolecules Characterize Living Things	210
Chemical groupings determine the structures of macromolecules	210
The structures of macromolecules reflect their functions	214
Investigatinglife Making Spider Silk	215
Experiment	215
Work with the data	215
Most macromolecules are formed by condensation and broken down by	216

hydrolysis	
3.2 The Function of a Protein Depends on Its Three-Dimensional Structure	220
Monomers of proteins link together to make the macromolecule	221
Peptide linkages form the backbone of a protein	223
The primary structure of a protein is its amino acid sequence	225
The secondary structure of a protein requires hydrogen bonding	226
The tertiary structure of a protein is formed by bending and folding	227
The quaternary structure of a protein consists of subunits	231
Shape and surface chemistry contribute to protein function	232
Environmental conditions affect protein structure	233
Experiment Primary Structure Specifies Tertiary Structure	230
Work with the data Primary Structure Specifies Tertiary Structure	231
Protein shapes can change	233
Molecular chaperones help shape proteins	235
3.3 Simple Sugars Are the Basic Structural Unit of Carbohydrates	237
Monosaccharides are simple sugars	238
Glycosidic linkages bond monosaccharides	239
Polysaccharides store energy and provide structural materials	240
Chemically modified carbohydrates contain additional functional groups	242
3.4 Lipids Are Defined by Their Solubility Rather Than by Chemical Structure	245
Fats and oils are triglycerides	245
Phospholipids form biological membranes	249
Some lipids have roles in energy conversion, regulation, and protection	250
Apply What You've Learned	259
4 Nucleic Acids and the Origin of Life	261
Investigatinglife Looking for Life	262
4.1 Nucleic Acid Structures Reflect Their Functions	263
Nucleic acids are informational macromolecules	263
Base pairing occurs in both DNA and RNA	266
DNA carries information and is expressed through RNA	271
The DNA base sequence reveals evolutionary relationships	272
Nucleotides have other important roles	273
4.2 The Small Molecules of Life Originated on Primitive Earth	275
Living organisms do not repeatedly come from inanimate nature	275
Experiment Disproving the Spontaneous Generation of Life	276
Life began in water	278
Prebiotic synthesis experiments model early Earth	278
Experiment Could Biological Molecules Have Been Formed from Chemicals Present in Earth's Early Atmosphere?	279
Life may have come from outside Earth	280
Investigatinglife Can We Find Evidence of Life on Mars?	281

Experiment	282
Work with the data	282
4.3 The Large Molecules of Life Originated from Small Molecules	284
Complex molecules could be formed from simpler ones on primitive Earth	284
RNA may have been the first biological catalyst	284
4.4 Cells Originated from Their Molecular Building Blocks	288
How did the first cells with membranes come into existence?	288
Some ancient cells left a fossil imprint	290
Apply What You've Learned	296
Part Two Cells	298
5 Cells: The Working Units of Life	299
Investigatinglife Natural Sunscreen	300
5.1 Cells Are the Fundamental Units of Life	301
What is the cell theory?	301
Cell size is limited by the surface areato-volume ratio	302
Microscopes reveal the features of cells	303
The cell membrane forms an outer boundary of every cell	309
Research tools Looking at Cells	303
Cells may be classified as either prokaryotic or eukaryotic	309
5.2 Prokaryotic Cells Are the Simplest Cells	312
What are the features of prokaryotic cells?	312
Specialized features are found in some prokaryotes	313
5.3 Eukaryotic Cells Contain Organelles	316
Compartmentalization is important to eukaryotic cell function	316
Organelles can be studied by microscopy or isolated for chemical analysis	316
Ribosomes are factories for protein synthesis	322
The nucleus contains most of the genetic information	322
Research tools Cell Fractionation	317
The endomembrane system is a group of interrelated organelles	324
Some organelles transform energy	331
There are several other membraneenclosed organelles	335
The cytoskeleton is important in cell structure and movement	339
Investigatinglife Discovering a New Organelle, the Tannosome	337
Experiment	337
Work with the data	338
Biologists can manipulate living systems to establish cause and effect	347
Experiment The Role of Microfilaments in Cell Movement—Showing Cause and Effect in Biology	347
Work with the data The Role of Microfilaments in Cell Movement—Showing Cause and Effect in Biology	347

5.4 Extracellular Structures Have Important Roles	349
What is the plant cell wall?	349
The extracellular matrix supports tissue functions in animals	351
5.5 Eukaryotic Cells Evolved in Several Steps	353
Internal membranes and the nuclear envelope probably came from the cell membrane	353
Some organelles arose by endosymbiosis	355
Apply What You've Learned	363
6 Cell Membranes	365
Investigatinglife Sweating and Membranes	366
6.1 Biological Membranes Are Lipid–Protein Bilayers	367
Lipids form the hydrophobic core of the membrane	368
Membrane proteins are asymmetrically distributed	370
Research tools Membrane Proteins Revealed by the Freeze-Fracture Technique	371
Experiment Rapid Diffusion of Membrane Proteins	372
Membranes are constantly changing	374
Cell membrane carbohydrates are recognition sites	374
6.2 The Cell Membrane Is Important in Cell Adhesion and Recognition	376
Cell recognition and adhesion involve proteins and carbohydrates at the cell surface	377
Three types of cell junctions connect adjacent cells	378
Cell membranes adhere to the extracellular matrix	380
6.3 Substances Can Cross Membranes by Passive Processes	383
Diffusion is the process of random movement toward a state of equilibrium	384
Simple diffusion takes place through the phospholipid bilayer	385
Osmosis is the diffusion of water across membranes	386
Diffusion may be aided by channel proteins	388
Carrier proteins aid diffusion by binding substances	391
Investigatinglife Aquaporins Increase Membrane Permeability to Water	392
Experiment	393
Work with the data	393
6.4 Active Transport across Membranes Requires Energy	395
Active transport is directional	396
Different energy sources distinguish different active transport systems	397
6.5 Large Molecules Enter and Leave a Cell through Vesicles	401
Macromolecules and particles enter the cell by endocytosis	401
Receptor-mediated endocytosis is highly specific	403
Exocytosis moves materials out of the cell	404
Apply What You've Learned	412

7 Cell Communication and Multicellularity	414
Investigatinglife A Signal for Bonding	415
7.1 Signals and Signaling Affect Cell Function	416
Cells receive several types of signals	416
A signal transduction pathway involves a signal, a receptor, and responses: Overview	418
7.2 Receptors Bind Signals to Initiate a Cellular Response	421
Receptors that recognize chemical signals have specific binding sites	421
Receptors can be classified by location and function	424
Intracellular receptors are located in the cytoplasm or the nucleus	429
7.3 The Response to a Signal Spreads through the Cell	432
The cell amplifies its response to ligand binding	432
Second messengers can amplify signals between receptors and target molecules	434
Signal transduction is highly regulated	440
7.4 Cells Change in Response to Signals in Several Ways	442
Ion channels respond to signals by opening or closing	442
Enzyme activities change in response to signals	442
Investigatinglife Is Oxytocin a “Trust”	445
Experiment	445
Work with the data	445
Signals can initiate DNA transcription	446
7.5 Adjacent Cells in a Multicellular Organism Can Communicate Directly	448
How do animal cells directly communicate?	448
Plant cells communicate through plasmodesmata	450
Modern organisms provide clues about the evolution of cell–cell interactions and multicellularity	450
Apply What You’ve Learned	459
Part Three Cells and Energy	461
8 Energy, Enzymes, and Metabolism	462
Investigatinglife How Aspirin Works	463
8.1 Physical Principles Underlie Biological Energy Transformations	464
There are two basic types of energy	465
There are two basic types of metabolism	466
The first law of thermodynamics: Energy is neither created nor destroyed	467
The second law of thermodynamics: Disorder tends to increase	467
Chemical reactions release or consume energy	469
Chemical equilibrium and free energy are related	471
8.2 ATP Plays a Key Role in Biochemical Energetics	474
ATP hydrolysis releases energy	474
ATP couples exergonic and endergonic reactions	476

8.3 Enzymes Speed Up Biochemical Transformations	479
To speed up a reaction, an energy barrier must be overcome	479
Enzymes bind specific reactants at their active sites	483
Enzymes lower the energy barrier but do not affect equilibrium	486
8.4 Enzymes Bring Substrates Together so Reactions Readily Occur	488
Enzymes can orient substrates	488
Enzymes can induce strain in the substrate	489
Enzymes can temporarily add chemical groups to substrates	489
Molecular structure determines enzyme function	490
Not all enzymes are proteins	491
Some enzymes require other molecules in order to function	492
The substrate concentration affects the reaction rate	492
8.5 Enzyme Activities Can Be Regulated	495
Enzymes can be regulated by inhibitors	497
Investigatinglife How Do Anti-Inflammatory Drugs Work as Enzyme Inhibitors?	499
Experiment	500
Work with the data	500
Allosteric enzymes are controlled via changes in shape	501
Allosteric effects regulate many metabolic pathways	503
Many enzymes are regulated through reversible phosphorylation	504
Enzymes are affected by their environment	505
Apply What You've Learned	512
9 Pathways That Harvest Chemical Energy	514
Investigatinglife A Weighty Matter	515
9.1 Cells Harvest Chemical Energy from Glucose Oxidation	516
How do cells obtain energy from glucose?	516
Redox reactions transfer electrons and energy	518
The coenzyme NAD ⁺ is a key electron carrier in redox reactions	519
An overview: Harvesting energy from glucose	521
9.2 In the Presence of Oxygen, Glucose Is Fully Oxidized	525
In the glycolysis pathway, glucose is partially oxidized	527
Pyruvate oxidation links glycolysis and the citric acid cycle	528
The citric acid cycle completes the oxidation of glucose to CO ₂	528
Pyruvate oxidation and the citric acid cycle are regulated by the concentrations of starting materials	530
9.3 Oxidative Phosphorylation Forms ATP	532
What are the steps in oxidative phosphorylation?	532
The respiratory chain transfers electrons and protons, and releases energy	533
ATP is made through chemiosmosis	534
Experiments demonstrate chemiosmosis	536

Experiment An Experiment Demonstrates the Chemiosmotic Mechanism	537
Investigatinglife Mitochondria, Genetics, and Obesity	539
Experiment	540
Work with the data	540
Some microorganisms use non-O ₂ electron acceptors	541
9.4 In the Absence of Oxygen, Some Energy Is Harvested from Glucose	543
Cellular respiration yields much more energy than fermentation	546
The yield of ATP is reduced by the impermeability of mitochondria to NADH	548
9.5 Metabolic Pathways Are Interrelated and Regulated	550
Catabolism and anabolism are linked	551
Catabolism and anabolism are integrated	552
Metabolic pathways are regulated systems	553
Apply What You've Learned	561
10 Photosynthesis: Energy from Sunlight	564
Investigatinglife Saving FACE	565
10.1 Photosynthesis Uses Light to Make Carbohydrates	566
Photosynthesis involves light and gas exchange	566
Experiments with isotopes show that O ₂ comes from H ₂ O in oxygenic photosynthesis	567
Investigatinglife What Is the Chemistry of Photosynthesis, and How Will Increasing CO ₂ in the Atmosphere Affect It?	568
Experiment	568
Work with the data	568
Photosynthesis involves two pathways	570
10.2 Photosynthesis Converts Light Energy into Chemical Energy	573
Light energy is absorbed by pigments in photosynthesis	573
Light absorption results in photochemical change	578
Reduction leads to ATP and NADPH formation	580
Chemiosmosis is the source of the ATP produced in photophosphorylation	582
10.3 Chemical Energy Trapped in Photosynthesis Is Used to Synthesize Carbohydrates	585
How were the steps in carbohydrate synthesis elucidated?	585
Experiment Tracing the Pathway of CO ₂	585
Work with the data Tracing the Pathway of CO ₂	586
The Calvin cycle is made up of three processes	588
Light stimulates the Calvin cycle	590
10.4 Plants Have Adapted Photosynthesis to Environmental Conditions	593
How do some plants overcome the limitations of CO ₂ fixation?	593
C ₃ plants undergo photorespiration but C ₄ plants do not	596
CAM plants also use PEP carboxylase	599
10.5 Photosynthesis Is an Integral Part of Plant Metabolism	602

Photosynthesis interacts with other metabolic pathways	602
Apply What You've Learned	609
Part Four Genes and Heredity	618
11 The Cell Cycle and Cell Division	619
Investigatinglife Immortal Cells	620
11.1 All Cells Derive from Other Cells	621
Prokaryotes divide by binary fission	624
Eukaryotic cells divide by mitosis followed by cytokinesis	626
11.2 The Eukaryotic Cell Division Cycle Is Regulated	628
Specific internal signals trigger events in the cell cycle	630
Investigatinglife What Controls the Reproduction of Cancer Cells?	630
Experiment	630
Work with the data	630
Growth factors can stimulate cells to divide	636
11.3 Eukaryotic Cells Divide by Mitosis	638
The centrosomes determine the plane of cell division	642
The spindle begins to form during prophase	642
Chromosome separation and movement are highly organized	644
Cytokinesis divides the cytoplasm	645
11.4 Cell Division Plays Important Roles in the Sexual Life Cycle	649
Sexual life cycles produce haploid and diploid cells	650
11.5 Meiosis Leads to the Formation of Gametes	653
Meiosis reduces the chromosome number	653
Chromatid exchanges during meiosis I generate genetic diversity	656
During meiosis homologous chromosomes separate by independent assortment	658
Meiotic errors lead to abnormal chromosome structures and numbers	662
The number, shapes, and sizes of the metaphase chromosomes constitute the karyotype	664
Polyploids have more than two complete sets of chromosomes	665
11.6 Cell Death Is Important in Living Organisms	668
Programmed cell death removes cells that do not benefit the organism	668
11.7 Unregulated Cell Division Can Lead to Cancer	671
Cancer cells differ from normal cells in important ways	671
Cancer cells lose control over the cell cycle and apoptosis	672
Experiment Does It Take Multiple Events to Trigger the Cancer Cell Cycle?	674
Cancer treatments target the cell cycle	676
Apply What You've Learned	616
12 Inheritance, Genes, and Chromosomes	679
Investigatinglife What Are the Rules of Inheritance?	680
12.1 Inheritance of Genes Follows Mendelian Laws	681

Mendel's laws arose from controlled crosses of pea plants	681
Mendel's first experiments involved monohybrid crosses	683
Investigatinglife Mendel's Monohybrid Experiments	685
Experiment	686
Work with the data	686
Mendel's first law states that the two copies of a gene segregate	687
Mendel verified his hypotheses by performing test crosses	691
Experiment Homozygous or Heterozygous?	691
Mendel's second law states that copies of different genes assort independently	693
Probability can be used to predict inheritance	695
Mendel's laws can be observed in human pedigrees	698
12.2 Alleles Can Produce Multiple Phenotypes	703
New alleles arise by mutation	703
Many genes have multiple alleles	703
Dominance is not always complete	704
In codominance, both alleles at a locus are expressed	706
Some alleles have multiple phenotypic effects	708
12.3 Genes Can Interact to Produce a Phenotype	710
Hybrid vigor results from new gene combinations and interactions	711
The environment affects gene action	713
Most complex phenotypes are determined by multiple genes and the environment	714
12.4 Genes Are Carried on Chromosomes	717
Linked genes are inherited together	717
Genes can be exchanged between chromatids and mapped	721
Experiment Some Alleles Do Not Assort Independently	717
Work with the data Some Alleles Do Not Assort Independently	719
Linkage is revealed by studies of the sex chromosomes	724
12.5 Some Eukaryotic Genes Are Outside the Nucleus	733
12.6 Prokaryotes Can Transmit Genes by Mating	735
Bacteria exchange genes by conjugation	735
Bacterial conjugation is controlled by plasmids	737
Apply What You've Learned	744
13 DNA and Its Role in Heredity	746
Investigatinglife Targeting DNA Replication in Cancer Therapy	747
13.1 Experiments Revealed the Function of DNA as Genetic Material	748
Circumstantial evidence indicates that the genetic material is DNA	748
DNA from one type of bacterium genetically transforms another type	748
Experiment Genetic Transformation	749
Experiment Genetic Transformation by DNA	751
Viral infection experiments confirmed that DNA is the genetic material	752

Eukaryotic cells can also be genetically transformed by DNA	756
Experiment The Hershey–Chase Experiment	754
13.2 DNA Has a Structure That Suits Its Function	758
How did Watson and Crick deduce the structure of DNA?	758
Four key features define DNA structure	761
The double-helical structure of DNA is essential to its function	764
13.3 DNA Is Replicated Semiconservatively	766
An elegant experiment demonstrated that DNA replication is semiconservative	767
There are two steps in DNA replication	768
DNA polymerases add nucleotides to the growing chain	769
Investigatinglife The Meselson–Stahl Experiment	770
Experiment	770
Work with the data	771
Many other proteins assist with DNA polymerization	774
The two DNA strands grow differently at the replication fork	775
Telomeres are not fully replicated and are prone to repair	779
13.4 Errors in DNA Can Be Repaired	784
Repair mechanisms preserve DNA	784
13.5 The Polymerase Chain Reaction Amplifies DNA	786
The polymerase chain reaction can make multiple copies of a DNA sequence	786
Apply What You’ve Learned	794
14 From DNA to Protein: Gene Expression	796
Investigatinglife Employing the Genetic Code to Combat Superbugs	797
14.1 Genes Code for Proteins	798
Observations in humans led to the proposal that genes determine enzymes	798
Experiments on bread mold established that genes determine enzymes	799
Experiment One Gene, One Enzyme	801
Work with the data One Gene, One Enzyme	803
One gene determines one polypeptide	803
14.2 Information Flows from Genes to Proteins	805
Three types of RNA have roles in the information flow from DNA to protein	805
In some cases, RNA determines the sequence of DNA	807
14.3 DNA Is Transcribed to Produce RNA	809
RNA polymerases share common features	809
Transcription occurs in three steps	810
The genetic code specifies which amino acids will be included in the polypeptide	813
Investigatinglife Deciphering the Genetic Code	815
Experiment	801
Work with the data	817

14.4 Eukaryotic Pre-mRNA Transcripts Are Processed prior to Translation	819
Noncoding sequences called introns often appear between genes in eukaryotic chromosomes	822
Pre-mRNA processing prepares the mRNA transcript for translation	823
14.5 The Information in mRNA Is Translated into Proteins	827
A transfer RNA carries a specific amino acid and binds to a specific mRNA codon	827
Each tRNA is specifically attached to an amino acid	828
The ribosome is the workbench for translation	829
Translation takes place in three steps	831
Polysome formation increases the rate of protein synthesis	837
14.6 Polypeptides Can Be Modified and Transported during or after Translation	839
How are proteins directed to their cellular destinations?	839
Mitochondria and chloroplasts make some of their own proteins and import others	842
Many proteins are modified after translation	842
Experiment Testing the Signal	841
Apply What You've Learned	850
15 Gene Mutation and Molecular Medicine	852
Investigatinglife The Angelina Jolie Effect	853
15.1 Mutations Are Heritable Changes in DNA	854
Mutations have different phenotypic effects	854
Point mutations are changes in single nucleotides	859
Chromosomal mutations are extensive changes in the genetic material	861
Retroviruses and transposons can cause loss-of-function mutations or duplications	863
Mutations can be spontaneous or induced	863
Mutagens can be natural or artificial	865
Some base pairs are more vulnerable than others to mutation	866
Mutations have both benefits and costs	866
15.2 Mutations in Humans Can Lead to Diseases	869
Disease-causing mutations may make proteins dysfunctional	869
Disease-causing mutations may involve any number of base pairs	872
Expanding triplet repeats demonstrate the fragility of some human genes	873
Cancer often involves somatic mutations	874
Most diseases are caused by multiple genes and environment	876
15.3 Mutations Can Be Detected and Analyzed	878
Cleavage of DNA by restriction enzymes can be used to rapidly detect mutations	878
Gel electrophoresis separates DNA fragments	880
DNA fingerprinting combines PCR with restriction analysis and	882

electrophoresis	
Research tools Separating Fragments of DNA by Gel Electrophoresis	880
DNA analysis can be used to identify mutations that lead to disease	884
Genetic markers can be used to find disease-causing genes	885
Investigatinglife How Was the BRCA1 Gene Identified?	886
Experiment	886
Work with the data	887
15.4 Genetic Screening Is Used to Detect Disease	889
Genetic screening can be done by examining the phenotype	889
DNA testing is the most accurate way to detect abnormal genes	890
Research tools DNA Testing by Allele-Specific Oligonucleotide Hybridization	891
Allele-specific oligonucleotide hybridization can detect mutations	891
15.5 Genetic Diseases Can Be Treated	894
Genetic diseases can be treated by modifying the phenotype	894
Gene therapy offers the hope of specific treatments	896
Experiment Gene Therapy	898
Apply What You've Learned	905
16 Regulation of Gene Expression	907
Investigatinglife Gene Expression and Behavior	908
16.1 Prokaryotic Gene Expression Is Regulated in Operons	909
Regulating gene transcription conserves energy	911
Operons are units of transcriptional regulation in prokaryotes	913
Operator–repressor interactions control transcription in the lac and trp operons	914
Protein synthesis can be controlled by increasing promoter efficiency	916
RNA polymerases can be directed to particular classes of promoters	918
16.2 Eukaryotic Gene Expression Is Regulated by Transcription Factors	921
General transcription factors act at eukaryotic promoters	923
Specific proteins can recognize and bind to DNA sequences and regulate transcription	925
Specific protein–DNA interactions underlie binding	926
Transcription factors underlie cell differentiation	927
The expression of sets of genes can be coordinately regulated by transcription factors	927
16.3 Viruses Regulate Their Gene Expression during the Reproductive Cycle	930
Viruses undertake two kinds of reproductive cycles	930
Eukaryotic viruses can have complex life cycles	933
HIV gene regulation occurs at the level of transcription elongation	934
16.4 Epigenetic Changes Regulate Gene Expression	937
DNA methylation occurs at the promoter and silences transcription	937
Histone protein modifications affect transcription	939

Epigenetic changes can be induced by the environment	941
Investigatinglife Gene Expression and Behavior	941
Experiment	941
Work with the data	942
Global chromosome changes involve DNA methylation	942
16.5 Eukaryotic Gene Expression Can Be Regulated after Transcription	946
RNA splicing can result in different mRNAs being made from the same gene	946
Small RNAs are important regulators of gene expression	947
Translation of mRNA can be regulated by proteins	949
Apply What You've Learned	957
Part Five Genomes	959
17 Genomes	960
Investigatinglife The Dog Genome Project	960
17.1 Genomes Can Be Sequenced Rapidly	962
The base sequence of a short DNA fragment can be determined quickly	962
Genome sequences yield several kinds of information	966
Investigatinglife Comparative Analysis of the Tiger Genome	967
Experiment	968
Work with the data	968
17.2 Prokaryotic Genomes Are Compact	969
Prokaryotic genomes have distinctive features	969
The sequencing of prokaryotic and viral genomes has many potential benefits	970
Metagenomics allows us to describe new organisms and ecosystems	971
Some sequences of DNA can move about the genome	973
Will defining the genes required for cellular life lead to artificial life?	974
Experiment Using Transposon Mutagenesis to Determine the Minimal Genome	976
17.3 Eukaryotic Genomes Contain Many Types of Sequences	978
Genome sequences of model organisms provide important information	980
Eukaryotes have gene families	984
Eukaryotic genomes contain repetitive sequences	985
17.4 Human Biology Is Revealed through the Genome	990
Comparative genomics reveals the evolution of the human genome	991
Human genomics has potential benefits in medicine	992
17.5 Proteomics and Metabolomics Can Provide Insights beyond the Genome	996
The proteome is the complete set of proteins in a cell, tissue, or organism at a given time	996
Metabolomics is the study of chemical phenotype	998
Apply What You've Learned	1003
18 Recombinant DNA and Biotechnology	1006
Investigatinglife DNA Technology Meets Medicine	1007

18.1 DNA from Different Sources Forms Recombinant DNA.	1008
Experiment Can DNA from Two Different Sources Be Recombined into a Single Functional DNA Molecule?	1009
18.2 There Are Several Ways to Insert DNA into Cells	1012
Selectable genetic markers are used to identify host cells containing recombinant DNA	1012
Genes can be inserted into prokaryotic or eukaryotic cells	1013
Inserted DNA is usually integrated into the host chromosome	1013
Reporter genes help select or identify host cells containing recombinant DNA	1016
Research tools Selection for Recombinant DNA	1016
18.3 Any Sequence of DNA Can Be Used for Cloning	1020
DNA for cloning can come from a library	1020
cDNA is made from mRNA transcripts	1021
Synthetic DNA can be made by PCR or by organic chemistry	1022
Research tools Constructing Libraries	1020
18.4 Several Tools Are Used to Modify DNA and Study Its Function	1025
Gene expression can be modulated by DNA technology	1025
DNA mutations can be created in the laboratory	1026
Genes can be inactivated and changed by CRISPR technology	1026
Complementary RNA can prevent the expression of specific genes	1029
Research tools Inactivating or Mutating a Gene by CRISPR	1026
DNA microarrays reveal RNA expression patterns	1031
18.5 DNA Can Be Manipulated for Human Benefit	1034
Cells can be turned into factories for a desired protein	1034
Medically useful proteins can be made using biotechnology	1036
DNA manipulation is changing agriculture	1037
Investigatinglife Producing TPA	1038
Experiment	1038
Work with the data	1039
Synthetic biology can create living factories for new products	1042
There is public concern about biotechnology	1043
Apply What You've Learned	1050
19 Genes, Development, and Evolution	1053
Investigatinglife Stem Cell Therapy	1054
19.1 The Four Major Processes of Development Are Determination, Differentiation, Morphogenesis, and Growth	1056
Development involves four distinct but overlapping processes	1057
As development proceeds cell fates become restricted	1058
Cell differentiation is sometimes reversible	1059
Experiment Cloning a Plant	1060
Research tools Cloning a Mammal	1063

Multipotent stem cells differentiate in response to environmental signals	1064
Investigatinglife Stem Cell Therapy	1065
Experiment	1065
Work with the data	1065
Pluripotent stem cells can be obtained in two ways	1066
19.2 Gene Expression Differences Determine Cell Fate and Cell Differentiation	1070
Cytoplasmic segregation can determine cell fate	1070
Inducers passing from one cell to another can determine cell fate	1072
Differential gene transcription is a hallmark of cell differentiation	1075
19.3 Gene Expression Determines Morphogenesis and Pattern Formation	1078
Morphogen gradients provide positional information	1078
Expression of transcription factor genes determines organ differentiation in plants	1080
A cascade of transcription factors establishes body segmentation in the fruit fly	1083
19.4 Changes in Gene Expression Underlie the Evolution of Development	1091
What is evo-devo?	1091
Developmental genes in distantly related organisms are similar	1092
Genetic switches govern how the genetic toolkit is used	1094
Modularity allows for differences in the patterns of gene expression	1095
19.5 Developmental Gene Changes Can Shape Evolution	1102
Mutations in developmental genes can cause major morphological changes	1102
Conserved developmental genes can lead to parallel evolution	1103
Apply What You've Learned	1111
Part Six The Processes and Patterns of Evolution	1113
20 Processes of Evolution	1114
Investigatinglife An Evolutionary Arms Race Between Bats and Moths	1115
20.1 Evolution Is Both Factual and the Basis of Broader Theory	1117
Darwin and Wallace introduced the idea of evolution by natural selection	1118
20.2 Mutation, Selection, Gene Flow, Genetic Drift, and Nonrandom Mating Result in Evolution	1122
Mutation generates genetic variation	1122
Selection acting on genetic variation leads to new phenotypes	1124
Natural selection increases the frequency of beneficial mutations in populations	1127
Investigatinglife Do Long Wing Tails Help Moths Escape Bat Predation?	1128
Experiment	1128
Work with the data	1129
Gene flow may change allele frequencies	1130
Genetic drift may cause large changes in small populations	1130
Nonrandom mating can change genotype or allele frequencies	1131
Experiment Sexual Selection in Action	1133

20.3 Evolution Can Be Measured by Changes in Allele Frequencies	1135
Research tools Calculating Allele and Genotype Frequencies	1135
Evolution will occur unless certain restrictive conditions exist	1137
Deviations from Hardy-Weinberg equilibrium show that evolution is occurring	1140
20.4 Selection Can Be Stabilizing, Directional, or Disruptive	1142
Stabilizing selection reduces variation in populations	1144
Directional selection favors one extreme	1145
Disruptive selection favors extremes over the mean	1146
20.5 Multiple Factors Account for the Maintenance of Variation in Populations	1149
Neutral mutations accumulate in populations	1149
Sexual recombination amplifies the number of possible genotypes	1149
Frequency-dependent selection maintains genetic variation within populations	1150
Heterozygote advantage maintains polymorphic loci	1151
Experiment A Heterozygote Mating Advantage	1152
Work with the data A Heterozygote Mating Advantage	1152
Genetic variation within species is maintained in geographically distinct populations	1153
20.6 Evolution Is Constrained by History and Trade-Offs	1156
Developmental processes constrain evolution	1156
Trade-offs constrain evolution	1158
Short-term and long-term evolutionary outcomes sometimes differ	1159
Apply What You've Learned	1166
21 Reconstructing and using Phylogenies	1169
Investigatinglife Using Phylogeny to Improve a Genetic Tool	1170
21.1 All of Life is Connected through its Evolutionary History	1172
Phylogenetic trees are the basis of comparative biology	1176
Derived traits provide evidence of evolutionary relationships	1177
21.2 Phylogeny Can Be Reconstructed from Traits of Organisms	1180
Parsimony provides the simplest explanation for phylogenetic data	1182
Phylogenies are reconstructed from many sources of data	1183
Mathematical models expand the power of phylogenetic reconstruction	1186
The accuracy of phylogenetic methods can be tested	1186
Investigatinglife Testing the Accuracy of Phylogenetic Analysis	1187
Experiment	1187
Work with the data	1188
21.3 Phylogeny Makes Biology Comparative and Predictive	1191
Phylogenetic trees can be used to reconstruct past events	1191
Phylogenies allow us to compare and contrast living organisms	1194
Phylogenies can reveal convergent evolution	1195

Ancestral states can be reconstructed	1196
Molecular clocks help date evolutionary events	1196
21.4 Phylogeny Is the Basis of Biological Classification	1201
Evolutionary history is the basis for modern biological classification	1202
Several codes of biological nomenclature govern the use of scientific names	1203
Apply What You've Learned	1211
22 Speciation	1213
Investigatinglife Rapid Speciation in African Lake Cichlids	1214
22.1 Species Are Reproductively Isolated Lineages on the Tree of Life	1215
We can recognize many species by their appearance	1215
Reproductive isolation is key	1218
The lineage approach takes a long-term view	1219
The different species concepts are not mutually exclusive	1219
22.2 Speciation Is a Natural Consequence of Population Subdivision	1221
Incompatibilities between genes can produce reproductive isolation	1221
Reproductive isolation develops with increasing genetic divergence	1223
22.3 Speciation May Occur through Geographic Isolation or in Sympatry	1226
Physical barriers give rise to allopatric speciation	1226
Sympatric speciation occurs without physical barriers	1229
22.4 Reproductive Isolation Is Reinforced When Diverging Species Come into Contact	1234
Prezygotic isolating mechanisms prevent hybridization	1234
Postzygotic isolating mechanisms result in selection against hybridization	1240
Investigatinglife Flower Color Reinforces a Reproductive Barrier in Phlox	1240
Experiment	1241
Work with the data	1240
Hybrid zones may form if reproductive isolation is incomplete	1241
22.5 Speciation Rates Are Highly variable across Life	1245
Several ecological and behavioral factors influence speciation rates	1245
Rapid speciation can lead to adaptive radiation	1247
Apply What You've Learned	1255
23 Evolution of Genes and Genomes	1257
Investigatinglife Evolutionary Theory helps us make Better Flu Vaccines	1258
23.1 DNA Sequences Record the History of Gene Evolution	1260
Evolution of genomes results in biological diversity	1260
Genes and proteins are compared through sequence alignment	1261
Research tools Amino Acid Sequence Alignment	1262
Models of sequence evolution are used to calculate evolutionary divergence	1263
Experimental studies examine molecular evolution directly	1268
23.2 Genomes Reveal Both Neutral and Selective Processes of Evolution	1270
Much of evolution is neutral	1273

Positive and purifying selection can be detected in the genome	1273
Experiment Convergent Molecular Evolution	1274
Work with the data Convergent Molecular Evolution	1276
Genome size also evolves	1277
23.3 Lateral Gene Transfer and Gene Duplication Can Produce Major Changes	1282
Lateral gene transfer can result in the gain of new functions	1282
Most new functions arise following gene duplication	1283
Some gene families evolve through concerted evolution	1286
23.4 Molecular Evolution Has Many Practical Applications	1290
Molecular sequence data are used to determine the evolutionary history of genes	1290
Gene evolution is used to study protein function	1291
In vitro evolution is used to produce new molecules	1292
Molecular evolution is used to study and combat diseases	1294
Investigatinglife Why Was the 1918-1919 Influenza Pandemic So Severe?	1294
Experiment	1295
Work with the data	1294
Apply What You've Learned	1301
24 The history of Life on Earth	1303
Investigatinglife When Giant Insects Ruled the Skies	1303
24.1 Events in Earth's History Can Be Dated	1305
Radioisotopes provide a way to date fossils and rocks	1307
Radiometric dating methods have been expanded and refined	1308
Scientists have used several methods to construct a geological time scale	1308
24.2 Changes in Earth's Physical Environment Have Affected the Evolution of Life	1311
Earth's continents and climates have changed over time	1312
Earth's climate has shifted between hot and cold conditions	1314
Volcanoes have occasionally changed the history of life	1315
Extraterrestrial events have triggered changes on Earth	1316
Oxygen concentrations in Earth's atmosphere have changed over time	1317
Investigatinglife The Relationship between Atmospheric Oxygen Concentration and Body Size in Insects	1321
Experiment	1321
Work with the data	1321
Extinction happens continuously, but mass extinctions result from sudden environmental changes	1321
Experiment What Factors Influence Extinction in Small Populations?	1323
Work with the data What Factors Influence Extinction in Small Populations?	1323
24.3 Major Events in the Evolution of Life Can Be read in the Fossil Record	1325
Several processes contribute to the paucity of fossils	1325

Precambrian life was small and aquatic	1326
Life expanded rapidly during the Cambrian period	1328
Many groups of organisms that arose during the Cambrian later diversified	1329
Geographic differentiation increased during the Mesozoic era	1334
Modern biotas evolved during the Cenozoic era	1335
The tree of life is used to reconstruct evolutionary events	1336
Apply What You've Learned	1340
Part Seven The Evolution of Diversity	1342
25 Bacteria, Archaea, and Viruses	1343
Investigatinglife Bacteria Light Up the Sea	1344
25.1 Bacteria and Archaea Are the Two Primary Divisions of Life	1345
The two prokaryotic domains differ in significant ways	1347
The small size of prokaryotes has hindered our study of their evolutionary relationships	1349
The nucleotide sequences of prokaryotes reveal their evolutionary relationships	1351
Lateral gene transfer can lead to discordant gene trees	1352
The great majority of prokaryote species have never been studied	1355
25.2 Prokaryote Diversity Reflects the Ancient Origins of Life	1357
Two early-branching lineages of bacteria live at very high temperatures	1357
Firmicutes include some of the smallest cellular organisms	1358
Actinobacteria include major pathogens as well as valuable sources of antibiotics	1360
Cyanobacteria were the first photosynthesizers	1361
Spirochetes move by means of axial filaments	1363
Chlamydias are extremely small parasites	1364
The proteobacteria are a large and diverse group	1365
Gene sequencing enabled biologists to differentiate Archaea from Bacteria	1367
Experiment What Is the Highest Temperature Compatible with Life?	1368
Work with the data What is the Highest Temperature Compatible with Life?	1368
Prokaryotic archaea live in extremely diverse environments	1369
25.3 Ecological Communities Depend on Prokaryotes	1373
Many prokaryotes form complex communities	1373
Microbiomes are critical to the health of many eukaryotes	1375
Investigatinglife How Do Bacteria Communicate with One Another?	1376
Experiment	1376
A small minority of bacteria are pathogens	1378
Prokaryotes have amazingly diverse metabolic pathways	1380
Prokaryotes play important roles in element cycling	1383
25.4 Viruses Have Evolved Many Times	1386

Many RNA viruses probably represent escaped genomic components of cellular life	1390
Some DNA viruses may have evolved from reduced cellular organisms	1392
Viruses can be used to fight bacterial infections	1393
Apply What You've Learned	1399
26 The Origin and Diversification of Eukaryotes	1401
Investigatinglife Predicting Toxic Red Tides	1402
26.1 Eukaryotes Acquired Features from Both Archaea and Bacteria	1403
The modern eukaryotic cell arose in several steps	1403
Chloroplasts have been transferred among eukaryotes several times	1406
26.2 Major Lineages of Eukaryotes Diversified in the Precambrian	1410
Alveolates have sacs under their cell membranes	1411
Stramenopiles typically have two unequal flagella, one with hairs	1416
Experiment The Role of Vacuoles in Ciliate Digestion	1416
Rhizarians typically have long, thin pseudopods	1421
Excavates began to diversify about 1.5 billion years ago	1423
Amoebozoans use lobe-shaped pseudopods for locomotion	1425
26.3 Protists Reproduce Sexually and Asexually	1432
Some protists reproduce without sex and have sex without reproduction	1432
Some protist life cycles feature alternation of generations	1433
26.4 Protists Are Critical Components of Many Ecosystems	1435
Phytoplankton are primary producers	1435
Some microbial eukaryotes are deadly	1435
Some microbial eukaryotes are endosymbionts	1437
We rely on the remains of ancient marine protists	1437
Investigatinglife Can Corals Reacquire Dinoflagellate Endosymbionts Lost to Bleaching?	1438
Experiment	1439
Work with the data	1438
Apply What You've Learned	1443
27 Plants without Seeds: From Water to Land	1445
Investigatinglife A Toxic Spill of Ancient Fossil Algae	1446
27.1 Primary Endosymbiosis Produced the First Photosynthetic Eukaryotes	1447
Work with the data The Phylogeny of Land Plants	1449
Several distinct clades of algae were among the first photosynthetic eukaryotes	1449
Investigatinglife Can Chlorella Algae Be Grown in Municipal Sewage Wastewater for Biofuel Production?	1452
Experiment	1453
Work with the data	1452
Two groups of green algae are the closest relatives of land plants	1453

There are ten major groups of land plants	1454
27.2 Key Adaptations Permitted Plants to Colonize Land	1457
Adaptations to life on land distinguish land plants from green algae	1457
Life cycles of land plants feature alternation of generations	1458
Nonvascular land plants live where water is readily available	1459
The sporophytes of nonvascular land plants are dependent on the gametophytes	1460
Liverworts are the sister clade of the remaining land plants	1462
Water and sugar transport mechanisms emerged in the mosses	1463
Hornworts have distinctive chloroplasts and stalkless sporophytes	1466
27.3 Vascular Tissues Led to Rapid Diversification of Land Plants	1469
Vascular tissues transport water and dissolved materials	1469
Vascular plants allowed herbivores to colonize the land	1470
The closest relatives of vascular plants lacked roots	1471
The lycophytes are sister to the other vascular plants	1473
Horsetails and ferns constitute a clade	1477
The vascular plants branched out	1478
Heterospory appeared among the vascular plants	1482
Experiment Atmospheric CO ₂ Concentrations and the Evolution of Megaphylls	1482
Apply What You've Learned	1491
28 The Evolution of Seed Plants	1493
Investigatinglife Brought Back from Extinction by a Seed	1493
28.1 Pollen, Seeds, and Wood Contributed to the Success of Seed Plants	1495
Features of the seed plant life cycle protect gametes and embryos	1496
The seed is a complex, well-protected package	1499
Investigatinglife William Beal's Seed Viability Study	1501
Experiment	1501
Work with the data	1501
A change in stem anatomy enabled seed plants to grow to great heights	1502
28.2 Once Dominant Gymnosperms Still Thrive in Some Environments	1503
There are four major groups of living gymnosperms	1503
Conifers have cones and lack swimming sperm	1506
28.3 Flowers and Fruits Led to Increased Diversification of Angiosperms	1511
Angiosperms have many shared derived traits	1511
The sexual structures of angiosperms are flowers	1512
Flower structure has evolved over time	1515
Angiosperms have coevolved with animals	1520
The angiosperm life cycle produces diploid zygotes nourished by triploid endosperms	1521

Experiment The Effect of Stigma Retraction in Monkeyflowers	1518
Fruits aid angiosperm seed dispersal	1523
Recent analyses have revealed the phylogenetic relationships of angiosperms	1526
28.4 Plants Play Critical Roles in Terrestrial Ecosystems	1534
Seed plants have been sources of medicine since ancient times	1534
Seed plants are our primary food source	1535
Apply What You've Learned	1543
29 The Evolution and Diversity of Fungi	1545
Investigatinglife The Accidental Discovery of Antibiotics	1546
29.1 Fungi Digest Food Outside Their Bodies	1547
Yeasts are unicellular, free-living fungi	1548
Multicellular fungi use hyphae to absorb nutrients	1548
Fungi are in intimate contact with their environment	1550
29.2 Fungi Are Decomposers, Parasites, Predators, or Mutualists	1552
Saprobic fungi are critical to the planetary carbon cycle	1552
Some fungi engage in parasitic or predatory interactions	1553
Experiment What Is the Origin of Amphibian-Killing Chytrids in North America?	1556
Mutualistic fungi engage in relationships that benefit both partners	1558
Endophytic fungi protect some plants from pathogens, herbivores, and stress	1563
29.3 Sex in Fungi Involves Multiple Mating Types	1565
Fungi reproduce both sexually and asexually	1566
Microsporidia are highly reduced, parasitic fungi	1568
Most chytrids are aquatic	1569
Some fungal life cycles feature separate fusion of cytoplasm and nuclei	1571
Arbuscular mycorrhizal fungi form symbioses with plants	1574
The dikaryotic condition is a synapomorphy of sac fungi and club fungi	1575
The sexual reproductive structure of sac fungi is the ascus	1577
The basidium is the sexual reproductive structure of club fungi	1579
29.4 Fungi Have Many Practical Uses	1582
Fungi are important in producing food and drink	1582
Fungi provide important weapons against diseases and pests	1583
Lichen diversity and abundance are indicators of air quality	1584
Fungi record and help remediate environmental pollution	1584
Reforestation may depend on mycorrhizal fungi	1584
Fungi are used as model organisms in laboratory studies	1585
Investigatinglife Using Fungi to Study Environmental Contamination	1585
Experiment	1586
Work with the data	1585
Apply What You've Learned	1592
30 Animal Origins and the Evolution of Body Plans	1594

Investigatinglife A Mysterious Animal Discovered in an Aquarium	1595
30.1 Some Animal Characteristics Evolved More Than Once	1596
Animal monophyly is supported by gene sequences and morphology	1597
A few basic developmental patterns differentiate major animal groups	1603
Experiment What Induces Choanoflagellates to Form Multicellular Colonies?	1602
30.2 Animals Diverged with Distinct Body Plans	1606
Most animals are symmetrical	1606
The structure of the body cavity influences movement	1608
Segmentation improves control of movement	1611
Appendages have many uses	1612
Nervous systems coordinate movement and allow sensory processing	1612
30.3 Animals Use Diverse Forms of Movement to Feed	1614
Filter feeders capture small prey	1615
Herbivores eat plants	1616
Predators and omnivores capture and subdue prey	1616
Parasites live in or on other organisms	1618
Detritivores live on the remains of other organisms	1618
30.4 Animal Life Cycles Involve Trade-Offs	1620
Many animal life cycles feature specialized life stages	1620
Most animal life cycles have at least one dispersal stage	1621
Parasite life cycles facilitate dispersal and overcome host defenses	1623
Some animals form colonies of genetically identical, physiologically integrated individuals	1624
No life cycle can maximize all benefits	1625
30.5 The Root of the Animal Tree Provides Clues to Early Animal Diversification	1629
Ctenophores are the sister group of all other animals	1629
Sponges are loosely organized animals	1631
Investigatinglife Reconstructing Animal Phylogeny from Protein-Coding Genes	1632
Experiment	1633
Work with the data	1633
Placozoans are abundant but rarely observed	1636
Cnidarians are specialized predators	1638
Some small groups of parasitic animals may be the closest relatives of bilaterians	1645
Apply What You've Learned	1652
31 Protostome Animals	1654
Investigatinglife Exploring the Diversity of Life on Earth	1655
31.1 Protostomes Account for More Than Half of All Described Species	1656
Cilia-bearing lophophores and trochophores evolved among the lophotrochozoans	1658

Ecdysozoans must shed their cuticles	1660
Arrow worms retain some ancestral developmental features	1662
31.2 Many Lophotrochozoans Have Ciliated Feeding Structures or Life Stages	1666
Most bryozoans and entoprocts live in colonies	1666
Flatworms, rotifers, and gastrotrichs are structurally diverse relatives	1667
Ribbon worms have a long, protrusible feeding organ	1673
Brachiopods and phoronids use lophophores to extract food from the water	1675
Annelids have segmented bodies	1677
Mollusks have undergone a dramatic evolutionary radiation	1682
31.3 Ecdysozoans Grow by Shedding Their Cuticles	1689
Several marine ecdysozoan groups have relatively few species	1689
Nematodes and their relatives are abundant and diverse	1692
31.4 Arthropods Are the Most Abundant and Diverse Group of Animals	1696
Arthropod relatives have fleshy, unjointed appendages	1697
Jointed appendages appeared in the trilobites	1698
Chelicerates have pointed, nonchewing mouthparts	1699
Mandibles and antennae characterize the remaining arthropod groups	1702
More than half of all described species are insects	1706
Investigatinglife How Many Unknown Species?	1708
Experiment	1708
Work with the data	1708
Key Features of Protostome Evolution	1714
Apply What You've Learned	1719
32 Deuterostome Animals	1721
Investigatinglife Which Came First, the Chicken or the Egg?	1722
32.1 Deuterostomes Include Echinoderms, Hemichordates, and Chordates	1723
Deuterostomes share early developmental patterns	1723
There are three major deuterostome clades	1723
Fossils shed light on deuterostome ancestors	1724
32.2 Echinoderms and Hemichordates Are Restricted to Marine Environments	1726
Echinoderms have unique structural features	1728
Hemichordates are wormlike marine deuterostomes	1731
32.3 Chordates Have a Dorsal Nerve Cord and a Notochord	1734
Adults of most lancelets and tunicates are sedentary	1736
A dorsal supporting structure replaces the notochord in vertebrates	1737
The phylogenetic relationships of jawless fishes are uncertain	1739
Jaws and teeth improved feeding efficiency	1741
Fins and swim bladders improved stability and control over locomotion	1742
32.4 Life on Land Contributed to Vertebrate Diversification	1748
Jointed limbs enhanced support and locomotion on land	1748

Amphibians usually require moist environments	1752
Amniotes colonized dry environments	1755
Reptiles adapted to life in many habitats	1758
Investigatinglife Have Shelled Eggs Re-Evolved among Viviparous Reptile Lineages?	1756
Experiment	1756
Work with the data	1757
Crocodylians and birds share their ancestry with the dinosaurs	1760
Feathers allowed birds to fly	1762
Mammals radiated after the extinction of non-avian dinosaurs	1766
32.5 Humans Evolved among the Primates	1776
Two major lineages of primates split late in the Cretaceous	1777
Bipedal locomotion evolved in human ancestors	1781
Human brains became larger as jaws became smaller	1783
Humans developed complex language and culture	1784
Apply What You've Learned	1790
Part Eight Flowering Plants: Form and Function	1792
33 The Plant Body	1793
Investigatinglife Bread of the Tropics	1794
33.1 The Plant Body Is Organized in a Distinctive Way	1795
Most angiosperms are either monocots or eudicots	1797
Plants develop differently than animals	1798
Apical-basal polarity and radial symmetry are characteristics of the plant body	1801
33.2 Plant Organs Are Made Up of Three Tissue Systems	1804
The dermal tissue system forms the outer covering of a plant	1805
The ground tissue system makes up most of the plant body	1805
The vascular tissue system develops into the plant's transport system	1808
33.3 Meristems Build a Continuously Growing Plant	1813
How do plants increase in size?	1813
Meristems generate the plant body	1814
Indeterminate primary growth originates in apical meristems	1815
The root apical meristem gives rise to the root cap and the root primary meristems	1817
The products of the root's primary meristems become root tissues	1817
The root system anchors the plant and takes up water and dissolved minerals	1821
The products of the stem's primary meristems become stem tissues	1824
The stem supports leaves and flowers but can have other roles	1825
Leaves are determinate organs produced by shoot apical meristems	1827
Many stems and roots undergo secondary growth	1829
Investigatinglife Understanding the Synthesis and Transport of Cyanogenic Glycosides	1829

Experiment	1830
Work with the data	1829
33.4 Domestication Has Altered Plant Form	1836
Apply What You've Learned	1842
34 Transport in Plants	1845
Investigatinglife Thirsty Rice	1846
34.1 Plants acquire Water and Minerals from the Soil	1847
Water potential differences govern the direction of water movement	1848
Water and ions move across the root cell's cell membrane	1850
Water and ions pass to the xylem by way of the apoplast and symplast	1852
34.2 Water and Minerals Are Transported in the Xylem	1856
Various hypotheses have proposed how water moves in the xylem	1856
The transpiration-cohesion-tension mechanism accounts for xylem transport	1857
Investigatinglife Improving Water-Use Efficiency in Rice	1859
Experiment	1859
Work with the data	1859
34.3 Stomata Control the Loss of Water and the Uptake of CO ₂	1861
Stomata control water loss and gas exchange	1861
The guard cells control the size of the stomatal opening	1863
34.4 Solutes Are Transported in the Phloem	1865
Sucrose and other solutes are carried in the phloem	1866
The pressure flow model accounts for translocation in the phloem	1868
Apply What You've Learned	1875
35 Plant Nutrition	1877
Investigatinglife Improving Plant Nutrition to Feed the World	1878
35.1 Plants Require Nutrients	1879
Plants require nutrients in different amounts	1879
Deficiency symptoms reveal inadequate nutrition	1881
Hydroponic experiments identified essential elements	1881
35.2 Plants Acquire Nutrients from the Soil	1884
Plants rely on growth to find nutrients	1884
Nutrient uptake and assimilation are regulated	1885
35.3 Soil Structure Affects Plant Nutrition	1886
Soil provides anchorage and nutrients for plants	1886
Soils form through the weathering of rock	1888
Soils are the source of plant nutrition	1889
Fertilizers add nutrients to soil	1890
35.4 Soil Organisms Increase Nutrient Uptake by Plant Roots	1893
Plants send signals to soil organisms	1893
Mycorrhizae expand the root system	1896

Soil bacteria are essential in getting nitrogen from air to plant cells	1896
Nitrogenase catalyzes nitrogen fixation	1896
Investigatinglife Mycorrhizal Fungi Can Replace Fertilizer in Cassava Cultivation	1897
Experiment	1898
Work with the data	1897
Biological nitrogen fixation does not always meet agricultural needs	1898
Ammonia formation is the first step in nitrogen assimilation by plants	1899
35.5 Carnivorous and Parasitic Plants Obtain Nutrients in Unique Ways	1901
Carnivorous plants supplement their mineral nutrition	1901
Parasitic plants take advantage of other plants	1902
The plant-parasite relationship is similar to plant-fungus and plant-bacteria associations	1904
Apply What You've Learned	1909
36 Regulation of Plant Growth	1911
Investigatinglife A Nobel Prize for a Plant Biologist	1911
36.1 Plants Develop in Response to the Environment	1913
Plant growth is regulated	1913
In early development, the seed germinates and forms a growing seedling	1914
Several hormones and photoreceptors help regulate plant growth	1917
Genetic screens have increased our understanding of plant signal transduction	1918
Research tools A Genetic Screen	1919
36.2 Gibberellins and Auxin Have Diverse Effects but a Similar Mechanism of Action	1922
Gibberellins have many effects on plant growth and development	1924
Auxin plays a role in differential plant growth	1925
Investigatinglife The Darwins' Phototropism Experiment	1926
Experiment	1927
Work with the data	1927
Auxin affects plant growth in several ways	1930
At the molecular level, auxin and gibberellins act similarly	1933
36.3 Other Plant Hormones Have Diverse Effects	1938
Cytokinins are active from seed to senescence	1938
Ethylene is a gaseous hormone that hastens leaf senescence and fruit ripening	1939
Brassinosteroids are plant steroid hormones	1941
36.4 Photoreceptors Initiate Developmental Responses to Light	1943
What are plant photoreceptors?	1943
Phototropins, cryptochromes, and zeaxanthin are blue-light receptors	1943
Phytochromes mediate the effects of red and far-red light	1945
Experiment Sensitivity of Seeds to Red and Far-Red Light	1946
Work with the data Sensitivity of Seeds to Red and Far-Red Light	1946

Phytochrome stimulates gene transcription	1949
Circadian rhythms are entrained by light reception	1950
Apply What You've Learned	1952
37 Reproduction in Flowering Plants	1958
Investigatinglife What Signals Flowering?	1959
37.1 Most Angiosperms Reproduce Sexually	1960
How does the flower function as a structure for sexual reproduction?	1960
Flowering plants have microscopic gametophytes	1962
A pollen tube delivers sperm cells to the embryo sac	1964
Many flowering plants control pollination or pollen tube growth to prevent inbreeding	1965
Angiosperms perform double fertilization	1966
Embryos develop within seeds contained in fruits	1968
Seed development is under hormonal control	1971
37.2 Hormones and Signaling Determine the Transition from the Vegetative to the Reproductive State	1974
Flowering occurs at specific places and specific times	1974
A cascade of gene expression leads to flowering	1976
Photoperiodic cues can initiate flowering	1977
Plants vary in their responses to photoperiodic cues	1978
Night length is a key photoperiodic cue that determines flowering	1979
The flowering stimulus originates in a leaf	1980
Investigatinglife The Flowering Signal	1981
Experiment	1981
Work with the data	1981
Experiment The Flowering Signal Moves from Leaf to Bud	1980
Work with the data The Flowering Signal Moves from Leaf to Bud	1980
Florigen is a small protein	1982
Flowering can be induced by temperature or gibberellin	1983
Some plants do not require an environmental cue to flower	1985
37.3 Angiosperms Can Reproduce Asexually	1988
Plants reproduce asexually by several methods	1988
Vegetative reproduction has a disadvantage	1991
Vegetative reproduction is important in agriculture	1991
In apomixis, flowers are used in asexual reproduction	1992
Apply What You've Learned	1998
38 Plant Responses to Environmental Challenges	2001
Investigatinglife Can Scientists Breed Disease-Resistant Wheat?	2002
38.1 Plants Respond to Pathogens with Constitutive and Induced Responses	2004
Physical barriers form constitutive defenses	2006

Plants can seal off infected parts to limit damage	2007
General and specific immunity both involve multiple responses	2008
Investigatinglife A Gene for Resistance to Wheat Rust	2009
Experiment	2009
Work with the data	2011
Specific immunity is genetically determined	2012
Specific immunity usually leads to the hypersensitive response	2013
Systemic acquired resistance is a form of long-term immunity	2014
38.2 Plants Have Mechanical and Chemical Defenses against Herbivores	2016
Plants have mechanical defenses against herbivores	2017
Plants produce constitutive chemical defenses against herbivores	2018
Plants respond to herbivory with induced defenses	2019
Jasmonates trigger a range of responses to wounding and herbivory	2020
Plants don't always win the arms race	2021
38.3 Plants Can Adapt to Environmental Stresses	2025
Plants can adapt to dry conditions	2025
Some plants grow in saturated soils	2029
Plants can respond to drought stress	2030
Plants can cope with temperature extremes	2032
Plants can adapt to salty soil	2033
Some plants can tolerate heavy metals	2034
Apply What You've Learned	2040
Part Nine Animals: Form and Function	2043
39 Physiology, Homeostasis, and Temperature Regulation	2044
Investigatinglife Heat Limits Physical Performance	2045
39.1 Animals Are Composed of Organs Built from Four Types of Tissues	2046
How would you build a multicellular animal?	2046
There are advantages and challenges to getting bigger	2046
There are four tissue types	2047
Organs are built from multiple tissues	2050
39.2 Physiological Systems Maintain Homeostasis of the Internal Environment	2053
The internal environment is the extracellular fluid that serves all the needs of the cells of the body	2053
Physiological systems are regulated to maintain homeostasis	2054
39.3 Biological Processes Are Temperature-Sensitive	2058
Temperature affects living systems	2058
Q10 is a measure of temperature sensitivity	2059
Animals acclimatize to seasonal temperatures	2060
Small changes in temperature can have large physiological effects	2061
Investigatinglife Can the Work Capacity of Muscle be Increased by Extracting Heat from the Palms of the Hands?	2061

Experiment	2061
Work with the data	2062
39.4 Body Temperature Depends on the Balance between Heat In and Heat Out of the Body	2064
Animals can be classified by their thermoregulatory characteristics	2064
Endotherms produce substantial amounts of metabolic heat	2065
Ectotherms and endotherms respond differently to changes in environmental temperature	2065
Energy budgets reflect adaptations for regulating body temperature	2068
Both ectotherms and endotherms control blood flow to the skin	2069
Some fish conserve metabolic heat	2071
Some ectotherms regulate metabolic heat production	2072
39.5 Body Temperature Is Regulated through Adaptations for Heat Production and Heat Loss	2074
Basal heat production rates of endotherms correlate with body size	2074
Endotherms respond to cold by producing heat and adapt to cold by reducing heat loss	2076
Evaporation of water can dissipate heat, but at a cost	2078
The mammalian thermostat uses feedback information	2078
Some animals conserve energy by turning down the thermostat	2080
Experiment The Hypothalamus Regulates Body Temperature	2080
Apply What You've Learned	2083
40 Animal Hormones	2088
Investigatinglife The Exercise Hormone	2088
40.1 Hormones Circulate Around the Body and Affect Target Cells	2090
There are multiple chemical communication systems in the body	2090
Endocrine signaling can act locally or at a distance	2091
Hormones are divided into three chemical groups	2093
Hormone action is mediated by receptors on or within their target cells	2095
Hormone action depends on the nature of the target cell and its receptors	2095
Hormone structure is conserved through evolution, but functions change	2097
40.2 The Endocrine System and Nervous System Work Together	2102
The pituitary is an interface between the nervous and endocrine systems	2102
Hypothalamic neurohormones control the anterior pituitary	2105
Negative feedback loops regulate hormone secretion	2107
Hormones influence the nervous system	2108
Investigatinglife How Could Irisin Mediate the Benefits of Exercise on Cognition?	2108
Experiment	2109
Work with the data	2109
40.3 Hormones Play Important Roles in Development	2111

Insect development consists of either complete or incomplete metamorphosis	2111
Experiments on insect development revealed hormonal signaling systems	2111
Three hormones regulate molting and maturation in arthropods	2111
Sex steroids control sexual development	2114
40.4 Hormones Regulate Metabolism and the Internal Environment	2120
Thyroxine stimulates many metabolic processes	2120
Three hormones regulate blood calcium concentrations	2124
PTH lowers blood phosphate levels	2126
Insulin and glucagon regulate blood glucose concentrations	2126
Experiment Effects of Exercise on Glucose Metabolism	2128
Work with the data Effects of Exercise on Glucose Metabolism	2128
The adrenal gland is two glands in one	2129
Many chemicals may act as hormones	2132
The pineal gland has a daily cycle of melatonin release	2132
Apply What You've Learned	2139
41 Immunology: Animal Defense	2141
Investigatinglife Vaccines and Immunity	2142
41.1 Animals Use Innate and Adaptive Mechanisms for Defense	2143
Innate defenses evolved before adaptive defenses	2144
Mammals have both innate and adaptive defenses	2146
Blood and lymph tissues play important roles in defense	2147
White blood cells play many defensive roles	2148
Immune system proteins bind pathogens or signal other cells	2150
41.2 Innate Defenses Are Nonspecific	2152
Specialized proteins and cells participate in innate immunity	2153
Inflammation is a coordinated innate response to infection or injury	2155
41.3 Adaptive Defenses Are Specific	2158
What are the key features of adaptive immunity?	2158
Macrophages and dendritic cells play a key role in activating the adaptive immune system	2159
Two types of adaptive immune responses interact	2160
Adaptive immunity develops as a result of clonal selection	2162
Clonal deletion helps the immune system distinguish self from nonself	2164
Immunological memory results in a secondary immune response	2164
Vaccines are an application of immunological memory	2165
Investigatinglife What Are the Mechanisms and Implications of Long-Lasting Immunity?	2166
Experiment	2166
Work with the data	2167
41.4 The Humoral Adaptive Response Involves Antibodies	2169
Antibody protein structure reflects function	2169

There are five classes of immunoglobulins	2171
Immunoglobulin diversity results from DNA rearrangements and other mutations	2172
The constant region is involved in immunoglobulin class switching	2174
41.5 The Cellular Adaptive Response Involves T Cells and Receptors	2176
MHC proteins present antigen to T cells, causing recognition	2177
T-helper cells and MHC II proteins contribute to the humoral immune response	2178
Cytotoxic T cells and MHC I proteins contribute to the cellular immune response	2180
Regulatory T cells suppress the humoral and cellular immune responses	2180
41.6 Malfunctions in Immunity Can Be Harmful	2183
The immune system mounts an excessive response in allergic reactions	2183
Autoimmune diseases are caused by reactions against self antigens	2185
AIDS is an immune deficiency disorder	2185
Apply What You've Learned	2193
42 Animal Reproduction	2196
Investigatinglife No Time to waste	2197
42.1 Asexual Reproduction is Efficient but Limits Genetic Variability	2198
Asexual reproduction limits genetic diversity	2198
Budding and regeneration produce new individuals by mitosis	2199
Parthenogenesis is the development of unfertilized eggs	2200
42.2 Sexual Reproduction Involves the Union of Haploid Egg and Sperm	2203
Gametogenesis produces eggs and sperm	2204
Fertilization is the union of sperm and egg	2207
Spawning and mating behaviors get eggs and sperm together	2211
Some individuals can function as both male and female	2213
The evolution of vertebrate reproductive systems parallels the move to land	2214
Animals with internal fertilization are distinguished by where the embryo develops	2215
42.3 Male Sex Organs Produce and May Deliver Sperm	2218
Semen is the product of the male reproductive system	2218
The penis and the scrotum are the male external genitalia	2222
Male sexual function is controlled by hormones	2223
42.4 Female Sex Organs Produce Eggs and Nurture Embryos	2226
Ovarian cycles produce mature eggs	2231
The uterine cycle prepares an environment for a fertilized egg	2231
Hormones control and coordinate the ovarian and uterine cycles	2232
FSH receptors determine which follicle ovulates	2233
In pregnancy, hormones from the extraembryonic membranes take over	2233
Breast feeding delays the return of the ovarian cycle	2234

Childbirth is triggered by hormonal and mechanical stimuli	2234
Investigatinglife The Control of Diapause in the Tammar Wallaby	2235
Experiment	2235
Work with the data	2236
Birth as well as reproduction is timed	2236
42.5 Fertility Can Be Controlled	2238
Humans use a variety of methods to control fertility	2238
Reproductive technologies help solve problems of infertility	2241
Apply What You've Learned	2248
43 Animal Development	2250
Investigatinglife Go With the Flow	2251
43.1 Fertilization Activates Development	2252
The sperm and the egg make different contributions to the zygote	2252
Fertilization sets the stage for determination	2252
43.2 Mitosis Divides up the Early Embryo	2257
Cleavage produces a multicellular embryo	2257
Cleavage in mammals is unique	2259
The fates of blastomeres depend on the cytoplasm they receive during cleavage	2262
Reproductive germ cells are determined early in cleavage	2262
43.3 Gastrulation Generates Multiple Tissue Layers	2265
Invagination at the vegetal pole initiates gastrulation in the sea urchin	2266
Frog gastrulation begins at the gray crescent	2268
The dorsal lip of the blastopore organizes the formation of the amphibian embryo	2269
Transcription factors and growth factors underlie the organizer's actions	2271
Properties of organizer cells change as they migrate from the dorsal lip	2272
Experiment The Dorsal Lip Induces Embryonic Organization	2271
The amount of yolk influences gastrulation	2271
Gastrulation in mammals is similar to avian gastrulation	2274
How is bilateral symmetry broken?	2274
Investigatinglife Does the Direction of Nodal Flow Influence the Development of Left-Right Asymmetry in the Mouse Embryo?	2274
Experiment	2274
Work with the data	2275
43.4 Organs Develop from the Three Germ Layers	2277
The organizer sets the stage for organogenesis	2277
Body segmentation is an early feature of vertebrate development	2279
Hox genes control differentiation along the anterior-posterior axis	2280
43.5 Extraembryonic Membranes Nurture Avian and Mammalian Embryos	2283
Birds develop four extraembryonic membranes	2283

The mammalian placenta forms from extraembryonic membranes	2284
Human gestation is divided into trimesters	2287
Apply What You've Learned	2294
44 Neurons, Glia, and Nervous Systems	2296
Investigatinglife Balancing the Brain	2297
44.1 Neurons and Glia Are Unique Cells of Nervous Systems	2298
Vertebrate neurons and macroglia originate in the embryonic neural tube	2299
The structure of neurons reflects their functions	2299
Glia are the “silent partners” of neurons	2302
44.2 Neurons Generate and Transmit Electric Signals	2306
Simple electrical concepts underlie neuronal function	2307
Activities of neurons are recorded as changes in membrane potential	2307
Research tools Measuring the Membrane Potential	2308
Ion transporters and channels generate membrane potentials	2307
Ion channels and their properties can be studied directly	2312
Research tools Using the Nernst Equation	2308
Gated ion channels alter membrane potential	2313
Work with the data Equilibrium Membrane Potential: The Goldman Equation	2311
Research tools Patch Clamping	2312
Graded changes in membrane potential can integrate information	2315
Sudden changes in Na ⁺ and K ⁺ channels generate action potentials	2314
Action potentials are conducted along axons without loss of signal	2318
Action potentials jump along myelinated axons	2321
44.3 Neurons Communicate with Other Cells	2324
The neuromuscular junction is a model chemical synapse	2324
The arrival of an action potential causes the release of neurotransmitter	2326
Synaptic functions involve many proteins	2326
The postsynaptic membrane responds to neurotransmitter	2326
Synapses can be excitatory or inhibitory	2327
The postsynaptic neuron sums excitatory and inhibitory input	2327
Electrical synapses are fast but do not integrate information well	2328
The action of a neurotransmitter depends on the receptor to which it binds	2329
To turn off responses, synapses must be cleared of neurotransmitter	2331
Investigatinglife Can Learning Be Restored in Mouse Models of Down Syndrome?	2329
Experiment	2330
Work with the data	2330
The diversity of receptors makes drug specificity possible	2331
44.4 Neurons and Glia Form Information-Processing Circuits	2333
Nervous systems range in complexity	2333

Reflexes are controlled by simple circuits involving sensory neurons, interneurons, and effectors	2335
The vertebrate brain is the seat of behavioral complexity	2337
Apply What You've Learned	2338
45 Sensory Systems	2348
Investigatinglife Seeing in the Dark	2349
45.1 Sensory Receptor Cells Convert Stimuli into Action Potentials	2350
Sensory transduction involves changes in membrane potentials	2350
Sensory receptor proteins act on ion channels	2351
Sensation depends on which neurons receive action potentials from sensory cells	2352
Many receptors adapt to repeated stimulation	2353
Investigatinglife How Do Pit Vipers "See" in the Dark?	2353
Experiment	2354
Work with the data	2354
45.2 Chemoreceptors Respond to Specific Molecules	2356
Olfaction is the sense of smell	2356
Some chemoreceptors detect pheromones	2358
The vomeronasal organ contains chemoreceptors	2359
Gustation is the sense of taste	2359
45.3 Mechanoreceptors Respond to Physical Forces	2362
Many different receptor cells respond to touch and pressure	2362
Mechanoreceptors are also found in muscles, tendons, and ligaments	2364
Hair cells are mechanoreceptors of the auditory and vestibular systems	2365
Auditory systems use hair cells to sense sound waves	2366
Flexion of the basilar membrane is perceived as sound	2369
Various types of damage can result in hearing loss	2371
The vestibular system uses hair cells to detect forces of gravity and momentum	2371
45.4 Photoreceptors Respond to Light	2374
Invertebrates have a variety of visual systems	2374
Image-forming eyes evolved independently in vertebrates and cephalopods	2375
The vertebrate retina receives and processes visual information	2377
Opsins are the universal photoreceptor molecule in animals	2378
Rod and cone cells are the photoreceptors of the vertebrate retina	2380
Experiment How Light Stimulates Rod Cells	2381
Information flows through layers of neurons in the retina	2384
Apply What You've Learned	2393
46 The Mammalian Nervous System: Structure and Higher Functions	2395
Investigatinglife The Brains of Taxi Drivers	2396
46.1 Functions Are Localized in the Nervous System	2397

Functional organization is based on flow and type of information	2398
The anatomical organization of the CNS emerges during development	2399
The spinal cord transmits and processes information	2402
The brainstem carries out many autonomic functions	2402
The core of the forebrain controls physiological drives, instincts, and emotions	2403
The cerebrum is responsible for complex behavior and consciousness	2405
Investigatinglife Place Cells Reveal Processes of Memory Consolidation during Sleep	2406
Experiment	2407
Work with the data	2408
The size of the human brain is off the curve	2411
46.2 Nervous System Functions Rely on Neural Circuits	2414
Pathways of the autonomic nervous system control involuntary physiological functions	2414
The visual system is an example of information integration by the cerebral cortex	2416
Three-dimensional vision results from cortical cells receiving input from both eyes	2419
Experiment What Does the Eye Tell the Brain?	2406
46.3 Higher Brain Functions Involve Integration of Multiple Systems	2422
Sleep and dreaming are reflected in electrical patterns in the cerebral cortex	2422
Language abilities are localized in the left cerebral hemisphere	2424
Some learning and memory can be localized to specific brain areas	2427
We still cannot answer the question “What is consciousness?”	2428
Apply What You’ve Learned	2435
47 Musculoskeletal Systems	2437
Investigatinglife Champion Jumpers	2437
47.1 Interactions of Actin and Myosin Cause Muscles to Contract	2439
Sliding filaments of actin and myosin cause skeletal muscle to contract	2440
Actin-myosin interactions cause filaments to slide	2443
Actin-myosin interactions are controlled by calcium ions	2445
Cardiac muscle is similar to and different from skeletal muscle	2449
Smooth muscle causes slow contractions of many internal organs	2451
47.2 Many Factors Affect Muscle Performance	2455
The strength of a muscle contraction depends on how many fibers are contracting and at what rate	2455
Muscle fiber types determine endurance and strength	2457
A muscle has an optimal length for generating maximum tension	2459
Investigatinglife What Is the Optimal Resting Position for the Jumping Muscle of the Frog?	2459
Experiment	2460

Work with the data	2461
Exercise increases muscle strength and endurance	2461
Muscle ATP supply limits performance	2462
Work with the data Does Heat Cause Muscle Fatigue?	2464
Insect muscle has the greatest rate of cycling	2466
47.3 Muscles and Skeletal Systems Work Together	2468
A hydrostatic skeleton consists of fluid in a muscular cavity	2468
Exoskeletons are rigid outer structures	2469
Vertebrate endoskeletons consist of cartilage and bone	2470
Bones develop from connective tissues	2473
Bones that have a common joint can work as a lever	2476
Apply What You've Learned	2484
48 Gas Exchange	2487
Investigatinglife The Breath of Life	2488
48.1 Respiratory Gas Exchange is Governed by Physical Factors	2489
Diffusion of gases is driven by partial pressure differences	2489
Fick's law applies to all systems of gas exchange	2490
Air is a better respiratory medium than water	2491
High temperatures create respiratory problems for aquatic animals	2492
O ₂ availability decreases with altitude	2493
CO ₂ is lost by diffusion	2493
48.2 Enhancing Diffusion Maximizes Respiratory Gas Exchange	2495
Respiratory organs have large surface areas	2495
Ventilation and perfusion of gas exchange surfaces maximize partial pressure gradients	2496
Insects have airways throughout their bodies	2497
Fish gills use countercurrent flow to maximize gas exchange	2497
Birds use unidirectional ventilation to maximize gas exchange	2500
Tidal ventilation produces dead space that limits gas exchange efficiency	2505
Research tools Measuring Lung Ventilation	2507
Work with the data Measuring Lung Ventilation	2508
Small residual volume prevents the bends in seals	2508
48.3 Humans Have Tidal Respiration	2510
Lungs are ventilated through a branching system of airways	2512
Respiratory tract secretions aid ventilation	2512
Lungs are ventilated by pressure changes in the thoracic cavity	2513
48.4 Respiratory Gases Are Transported by the Blood	2517
Red blood cells are produced in the bone marrow	2517
Hemoglobin combines reversibly with O ₂	2518
Myoglobin holds an O ₂ reserve	2520
Hemoglobin's affinity for O ₂ is variable	2521

Investigatinglife Seals Are Champion Breath-hold Divers	2522
Experiment	2523
Work with the data	2525
Most CO ₂ is transported as bicarbonate ions in the blood	2527
48.5 Breathing Is Homeostatically Regulated	2530
Breathing is controlled in the brainstem	2530
Regulating breathing requires feedback	2531
Apply What You've Learned	2539
49 Circulatory Systems	2541
Investigatinglife Athletes with Big Hearts	2542
49.1 Circulatory Systems Serve Many Functions	2543
Some animals do not have a circulatory system	2543
Circulatory systems can be open or closed	2544
Open circulatory systems move extracellular fluid	2544
Closed circulatory systems circulate blood through a system of blood vessels	2546
49.2 Vertebrate Circulatory Systems Evolved from Single to Double Circuits	2548
Circulation in fishes is a single circuit	2549
Lungfishes evolved a gas-breathing organ	2550
Amphibians have partial separation of systemic and pulmonary circulation	2551
Reptiles have exquisite control of pulmonary and systemic circulation	2552
Birds and mammals have fully separated pulmonary and systemic circuits	2552
49.3 Heart Function Depends on Properties of Cardiac Muscle	2556
Blood flows from right heart to lungs to left heart to body	2558
The heartbeat originates in the cardiac muscle	2560
A conduction system coordinates the contraction of heart muscle	2563
HCM can disrupt conduction	2568
Investigatinglife Silencing Mutant Myosin Genes	2566
Experiment	2566
Work with the data	2567
Electrical properties of ventricular muscles sustain heart contraction	2568
The ECG records the electrical activity of the heart	2570
49.4 Circulatory System Functions Depend on Blood and Blood Vessels	2572
Red blood cells transport respiratory gases	2573
Platelets are essential for blood clotting	2574
Arteries withstand high pressure, arterioles control blood flow	2574
Materials are exchanged in capillary beds by filtration, osmosis, and diffusion	2575
Blood flows back to the heart through veins	2580
Lymphatic vessels return interstitial fluid to the blood	2582
Vascular disease is a killer	2582
49.5 The Circulation is Controlled by Hormonal and Neural Signals	2586

Autoregulation matches local blood flow to local need	2587
Arterial pressure is regulated by hormonal and neural mechanisms	2588
Apply What You've Learned	2597
50 Nutrition, Digestion, and Absorption	2600
Investigatinglife Thrifty Phenotypes	2601
50.1 Food Provides Energy As Well As Materials for Biosynthesis	2602
Energy needs and expenditures can be measured	2603
Sources of energy are stored in the body	2605
Food provides carbon skeletons for biosynthesis	2606
Animals need mineral elements for a variety of functions	2608
Animals must obtain vitamins from food	2610
Nutrient deficiencies result in diseases	2611
50.2 Diverse Adaptations Support Ingestion and Digestion of Food	2614
The food of herbivores is often low in energy and hard to digest	2615
Carnivores must find, capture, and kill prey	2615
Vertebrate species have distinctive teeth	2615
Digestion usually begins in a body cavity	2616
Tubular guts have an opening at each end	2617
Digestive enzymes break down complex food molecules	2620
The gut microbiome contributes to digestion	2621
Investigatinglife How Does the Gut Microbiome Contribute to Obesity and Metabolic Disease?	2621
Experiment	2621
Work with the data	2622
50.3 The Vertebrate Gastrointestinal System is a Disassembly Line	2624
The vertebrate gut consists of concentric tissue layers	2625
Gut motility moves food through the gut and aids digestion	2626
Chemical digestion begins in the mouth and the stomach	2628
The stomach gradually releases its contents to the small intestine	2629
Most chemical digestion occurs in the small intestine	2630
Nutrients are absorbed in the small intestine	2634
Absorbed nutrients go to the liver	2635
Water and ions are absorbed in the large intestine	2635
Herbivores rely on their microbiota to digest cellulose	2636
50.4 Nutrient Availability is Controlled and Regulated	2640
Hormones control many digestive functions	2640
The liver stores and releases the molecules that fuel metabolism	2642
The liver produces lipoproteins: the good, the bad, and the ugly	2642
Insulin and glucagon control fuel metabolism	2643
The brain plays a major role in regulating food intake	2646
Experiment A Single-Gene Mutation Leads to Obesity in Mice	2648

Apply What You've Learned	2654
51 Salt and Water Balance and Nitrogen Excretion	2657
Investigatinglife How Vampire Bats Use Blood as Fast Food	2658
51.1 Excretory Systems Regulate Osmotic and Ionic Concentrations	2659
Osmosis causes water to enter or to leave cells	2659
Excretory systems control extracellular fluid osmolarity and composition	2660
Aquatic invertebrates are either ionic conformers or regulators	2660
Vertebrates are osmoregulators and ionic regulators	2662
51.2 Animals Excrete Nitrogen as Ammonia, Urea, or Uric Acid	2664
Ammonia is toxic	2664
Urea is highly soluble in water	2665
Uric acid is not very soluble in water	2665
Most species produce more than one nitrogenous waste	2666
51.3 Invertebrate Excretory Systems Use Filtration, Secretion, and Reabsorption	2668
Protonephridia of flatworms excrete water and conserve salts	2668
Metanephridia of annelids process coelomic fluid	2670
Malpighian tubules of insects use active transport to excrete wastes	2671
51.4 The Nephron Is the Basic Functional Unit of Vertebrate Excretory Systems	2673
Marine fishes must conserve water	2673
Terrestrial amphibians and reptiles must avoid desiccation	2674
Mammals can produce highly concentrated urine	2674
The nephron is the functional unit of the vertebrate kidney	2675
Blood is filtered into Bowman's capsule	2676
The renal tubules convert glomerular filtrate to urine	2676
51.5 The Mammalian Kidney Can Produce Concentrated Urine	2679
Kidneys produce urine and the bladder stores it	2679
Nephrons have a regular arrangement in the kidney	2681
Most of the glomerular filtrate is reabsorbed by the proximal convoluted tubule	2682
The loop of Henle creates a concentration gradient in the renal medulla	2683
Investigatinglife How Can Vampire Bats Use Blood as Fast Food?	2683
Experiment	2684
Work with the data	2684
Water permeability of kidney tubules depends on water channels	2686
The distal convoluted tubule fine-tunes the composition of the urine	2687
Urine is concentrated in the collecting duct	2687
The kidneys help regulate acid-base balance	2687
Kidney failure is treated with dialysis	2690
51.6 Kidney Function Is Regulated	2692
Glomerular filtration rate is regulated	2692
Regulation of GFR uses feedback information from the distal tubule	2694

Blood osmolarity and blood pressure are regulated by ADH	2694
The heart produces a hormone that helps lower blood pressure	2698
Experiment ADH Induces Insertion of Aquaporins into Cell Membranes	2696
Apply What You've Learned	2704
52 Animal Behavior	2706
Investigatinglife An Instinct to Learn	2707
52.1 Ethology Led to Modern Behavioral Biology	2708
Conditioned reflexes are a simple behavioral mechanism	2708
Ethologists focused on the behavior of animals in their natural environment	2710
Ethologists probed the causes of behavior	2711
52.2 Behavior Can Be Genetically Determined	2714
Single gene mutations can alter behavioral phenotypes	2714
Knockout experiments reveal the roles of specific genes	2715
Gene cascades can control complex behavioral phenotypes	2715
52.3 Behavior Can Be Studied Developmentally	2718
Hormones can determine behavioral potential and timing	2718
Some behaviors can be acquired only at certain times	2719
Birdsong learning involves genetics, imprinting, development, and social interactions	2720
Investigatinglife Practice Makes Perfect	2723
Experiment	2723
Work with the data	2723
The timing and expression of birdsong are under hormonal control	2725
52.4 Selective Pressures Shape Behavior	2727
Animals are faced with many choices	2727
Behaviors have costs and benefits	2728
Territorial behavior carries significant costs	2728
Experiment The Costs of Defending a Territory	2728
Foraging behavior has costs and benefits	2733
52.5 Behavior Can Be Studied Mechanistically	2736
Biological rhythms coordinate behavior with environmental cycles	2736
Animals must find their way around their environment	2740
Animals use multiple modalities to communicate	2745
Experiment A Time-Compensated Solar Compass	2743
52.6 Social Interactions Shape the Evolution of Behavior	2750
Mating systems evolve to maximize fitness	2750
Fitness can include more than your own offspring	2751
Eusociality is the extreme result of kin selection	2754
Group living has benefits and costs	2755
Can the concepts of sociobiology be applied to humans?	2758
Apply What You've Learned	2763

Part Ten Ecology	2766
53 The Physical Environment and Biogeography of Life	2767
Investigatinglife The Largest Experiment on Earth	2768
53.1 Ecology Is the Study of the Interrelationships among Organisms and the Environment	2769
Modern ecology has a more “use-inspired” focus	2769
Ecology is studied at many levels of organization	2770
Answering ecological questions requires observations, experiments, and models	2772
53.2 Global Climate Is a Fundamental Component of the Physical Environment	2774
Solar radiation drives global climate patterns	2774
Earth is a sphere, creating latitudinal variation in global temperature and precipitation	2775
Earth spins on an axis, producing prevailing winds and ocean currents	2778
The tilt of Earth’s axis and its orbit result in seasons	2780
53.3 Topography, Vegetation, and Humans Modify the Physical Environment	2783
Earth’s topography affects the local and regional physical environment	2783
Vegetation affects the local and regional physical environment, especially climate	2786
Humans have transformed their physical environment, including urban climate	2787
53.4 Biogeography Is the Study of How Organisms Are Distributed on Earth	2790
Patterns of biogeography are interconnected across a hierarchy of spatial and temporal scales	2790
Terrestrial biomes reflect global patterns of temperature and precipitation	2792
Biogeographic regions reflect evolutionary isolation	2797
Diversity varies with latitude and longitude	2801
Geographic variation in diversity is explained by multiple factors	2801
53.5 Geographic Area and Humans Affect Regional Species Diversity	2804
Humans exert a powerful influence on biogeographic patterns	2806
Investigatinglife The Largest Experiment on Earth	2807
Experiment	2807
Work with the data	2807
Apply What You’ve Learned	2811
54 Populations	2814
Investigatinglife Earth’s Human Carrying Capacity	2814
54.1 Populations Show Dynamic Variation in Size over Space and Time	2816
Population dynamics are controlled by the physical environment, biological interactions, and dispersal	2818
Ecologists use a variety of approaches to estimate population size and extent	2821
Research tools The Mark-Recapture Method	2823
Work with the data Monitoring Tick Populations	2823

54.2 Population Growth Describes the Change in Population Size over Time	2825
Births increase and deaths decrease population size over time	2825
All populations have the potential for exponential growth	2827
Investigatinglife Will the Global Human Population Growth Rate Decline?	2828
Experiment	2829
Work with the data	2829
Logistic growth occurs as a population approaches its carrying capacity	2830
Factors limiting population growth can be density-dependent or density-independent	2832
Life tables keep track of demographic events	2832
54.3 Life History Is the Lifetime Pattern of Growth, Reproduction, and Survival	2839
Life history strategies can vary at species and population levels	2840
Life history strategies arise from constraints on growth, reproduction, and survival	2844
54.4 Population Biology Can Be Used in Conserving and Managing Populations	2848
Management plans must take life history strategies into account	2848
Management plans must be guided by the principles of population dynamics	2848
Knowledge of metapopulation dynamics helps us conserve species	2850
Apply What You've Learned	2856
55 Species Interactions	2858
Investigatinglife The Lionfish King	2859
55.1 Species Interactions Vary in Direction and Strength across a Continuum	2860
Species interactions are not always clear-cut	2863
Some interactions result in evolutionary change in the species involved	2864
55.2 Predation Is a Trophic Interaction in which Predators Benefit and Prey Are Harmed	2867
Carnivory results in a range of capture and avoidance mechanisms	2867
Herbivory is a widespread but specialized interaction	2872
Investigatinglife The Lionfish King	2871
Experiment	2872
Work with the data	2872
Most parasites specialize on hosts, and most hosts house many species of parasites	2873
Predator populations can cycle with their prey populations	2876
Predators can have dramatic effects on communities	2877
55.3 Competition is a Negative Interaction in which Species Overlap in the Use of Some Limiting Resource	2880
Resource partitioning allows species to coexist despite overlapping use of limiting resources	2882
The physical environment, disturbance, and predation can each alter the outcome of competition	2883

Competition can affect species' distributions	2884
55.4 Positive Interactions Occur When at Least One Species Benefits and None Are Harmed	2887
Positive interactions are more common in stressful environments	2888
Positive interactions can have dramatic effects on populations and communities	2889
Experiment Are Ants and Acacia Mutualists?	2890
Apply What You've Learned	2895
56 Communities	2898
Investigatinglife Rising from the Ashes	2899
56.1 Communities Are Groups of Interacting Species Occurring Together in Space and Time	2900
Ecologists often use a subset of species to define communities	2901
Species diversity and composition are important descriptors of community structure	2904
56.2 Community Membership Depends on Species Supply, Environmental Conditions, and Species Interactions	2909
Community membership depends on species supply	2911
Environmental conditions are critical to community membership	2911
Resident species can restrict or promote community membership	2912
56.3 Communities Are Complex Networks of Species Interactions That Vary in Strength and Direction	2914
Indirect interactions are important to community structure	2914
Strongly interacting species often regulate community structure	2916
Species with similar effects on one another may coexist by chance	2920
56.4 Communities Are Always Changing	2923
Change in communities can be caused by abiotic and biotic factors	2925
Succession is a process of change in communities over time	2926
Both facilitation and inhibition influence succession	2932
Investigatinglife Rising from the Ashes	2929
Experiment	2929
Work with the data	2931
Alternative successional pathways result in variations in community composition	2932
56.5 Relationships between Species Diversity and Community Function Are Often Positive	2935
Species diversity is associated with productivity and stability	2935
Diversity, productivity, and stability differ between natural and managed communities	2935
Apply What You've Learned	2941
57 Ecosystems	2943
Investigatinglife Food webs in an Acidic and warming ocean	2944
57.1 Ecosystem Science Considers How Energy and Nutrients Flow through	

Biotic and Abiotic Environments	2945
Energy flowing through ecosystems originates with sunlight and inorganic and organic compounds	2945
Nutrients cycling through ecosystems originate in soil, water, and the atmosphere	2947
57.2 Energy and Nutrients in Ecosystems Are First Captured by Primary Producers	2949
Net primary production is the amount of carbon remaining in plants after respiration	2949
Patterns of primary production vary with latitude and ecosystem type	2949
Rainfall and temperature largely control terrestrial primary production	2952
Light and nutrients combine to control aquatic primary production	2954
57.3 Food Webs Transfer Energy and Nutrients from Primary Producers to Consumers	2958
The amount of energy transferred within food webs depends on trophic efficiency	2960
Food webs are controlled by bottom-up and top-down forces	2961
The number of trophic levels can control the flow of energy through food webs	2962
57.4 Nutrient Cycling in Ecosystems Involves Chemical and Biological Transformations	2965
Water cycles rapidly around the globe	2966
The carbon cycle is being altered by human activities, resulting in climate change	2968
The nitrogen cycle is dominated by biotic processes	2973
Investigatinglife Food Webs in an Acidic and Warming Ocean	2971
Experiment	2972
Work with the data	2973
The global phosphorus cycle is dominated by geochemical processes	2976
The burning of fossil fuels affects the sulfur cycle	2976
57.5 Ecosystems Provide Important Services and Values to Humans	2979
The value of ecosystem services can be measured	2980
Apply What You've Learned	2986
58 A Changing Biosphere	2988
Investigatinglife Fatal Fungus Final Fate for Frogs	2988
58.1 Human Activities Are Changing the Biosphere, Resulting in Biodiversity Loss	2990
Biodiversity has great value to human society	2990
Diversity loss at one scale affects diversity loss at other scales	2991
Species diversity is being lost at unprecedented rates	2997
We can predict the effects of human activities on biodiversity	2998
58.2 Most Biodiversity Loss Is Caused by Habitat Loss and Degradation	3000

Habitat loss and degradation endanger species	3000
Overharvesting has driven many species to extinction and changed food webs	3003
Invasive predators, competitors, and pathogens threaten many species	3006
Investigatinglife Exploring the Decline of Central American Frogs	3008
Experiment	3009
Work with the data	3009
Species and ecosystems are already being affected by climate change	3009
58.3 Protecting Biodiversity Requires Conservation and Management Strategies	3015
Protected areas preserve habitat and curtail biodiversity loss	3016
Degraded ecosystems can be restored	3018
Captive breeding programs can maintain a few species	3020
Ending trade is crucial to saving some species	3021
Species invasions must be controlled or prevented	3021
Biodiversity can be conserved as a consequence of its economic value	3021
